

# Storytelling with Data

## Module 8: Effective visuals – grammar and layers

**Scott Spencer**  
Faculty and Lecturer  
Columbia University

# **Unanswered, or new, questions from discussion?**

# Agenda

Timeline for upcoming deliverables

Today's objectives

Communicating with color

The grammar of graphics

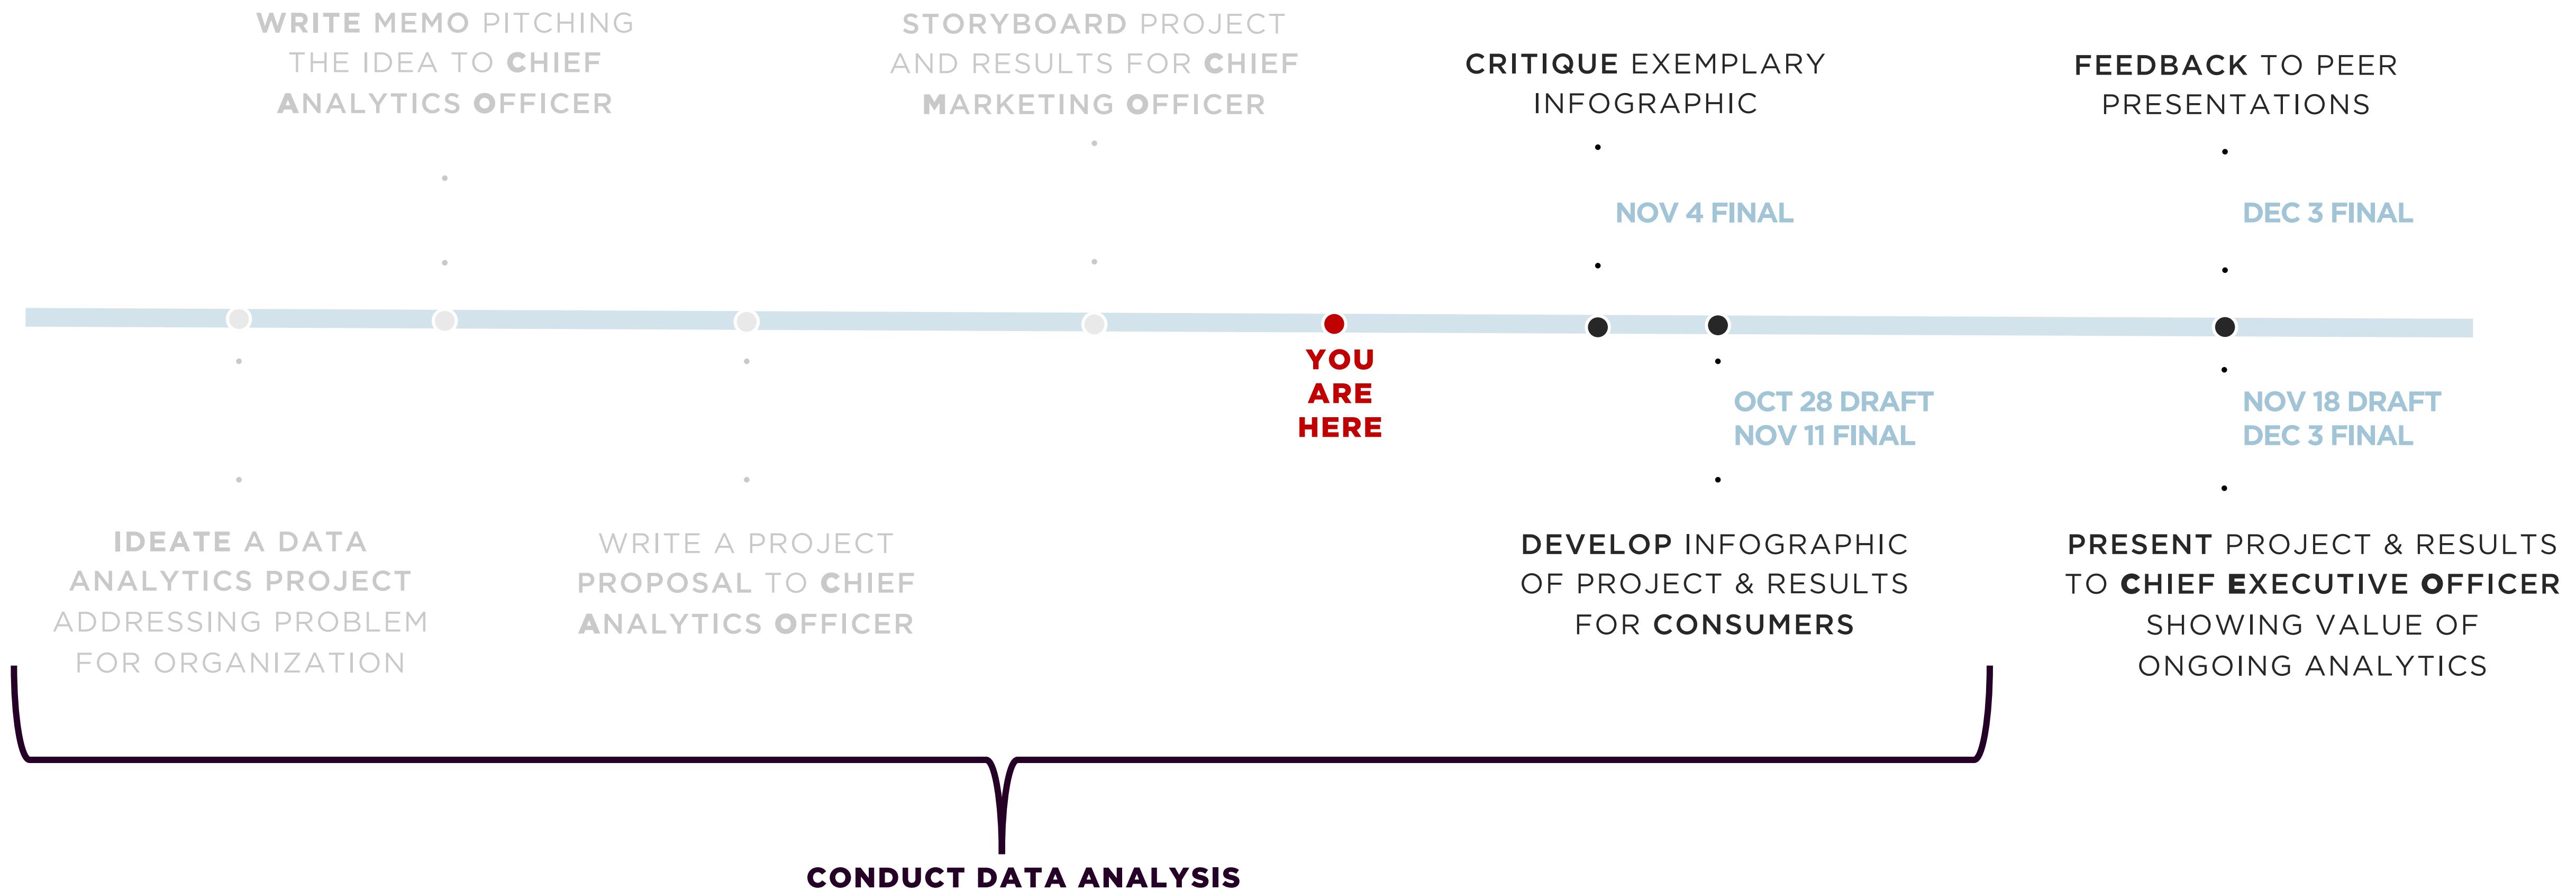

From graphics back to narrative

Complexity from common graphics

# Our project timeline

# Upcoming deliverables

**Information graphic** – reframe your story, this time building off the messages you built for the marketing team in order to craft an infographic that displays the results of the analytic work in a way that is accessible, engaging, and exciting for a **general or consumer audience**.

# Today's Objectives

# Objectives

1

Creating a visual narrative  
from common graphics

2

Consider the role of  
layering and hierarchy in  
graphic narrative

3

Building complexity from  
common graphics, examples

# **Communicating data with color**

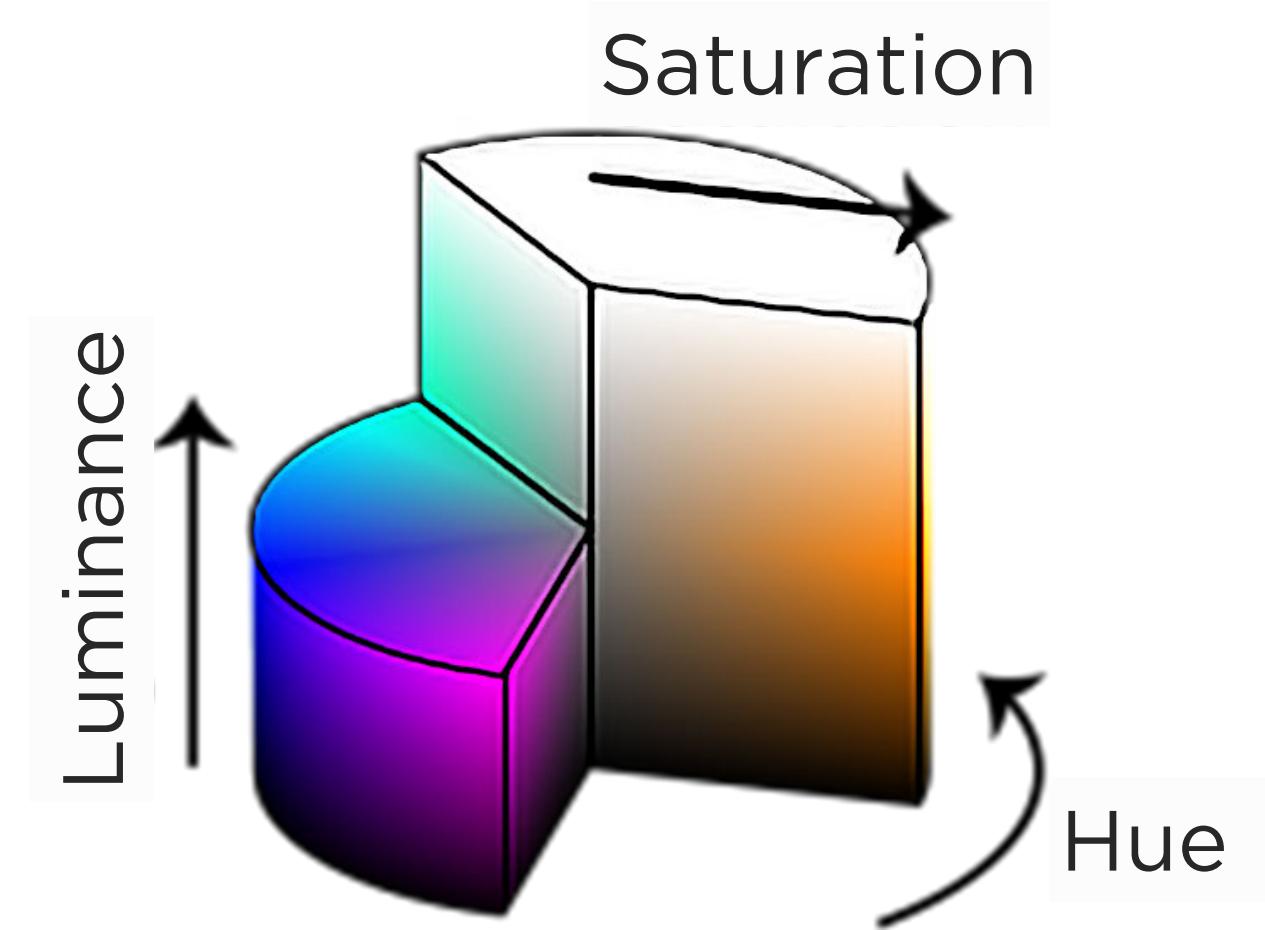

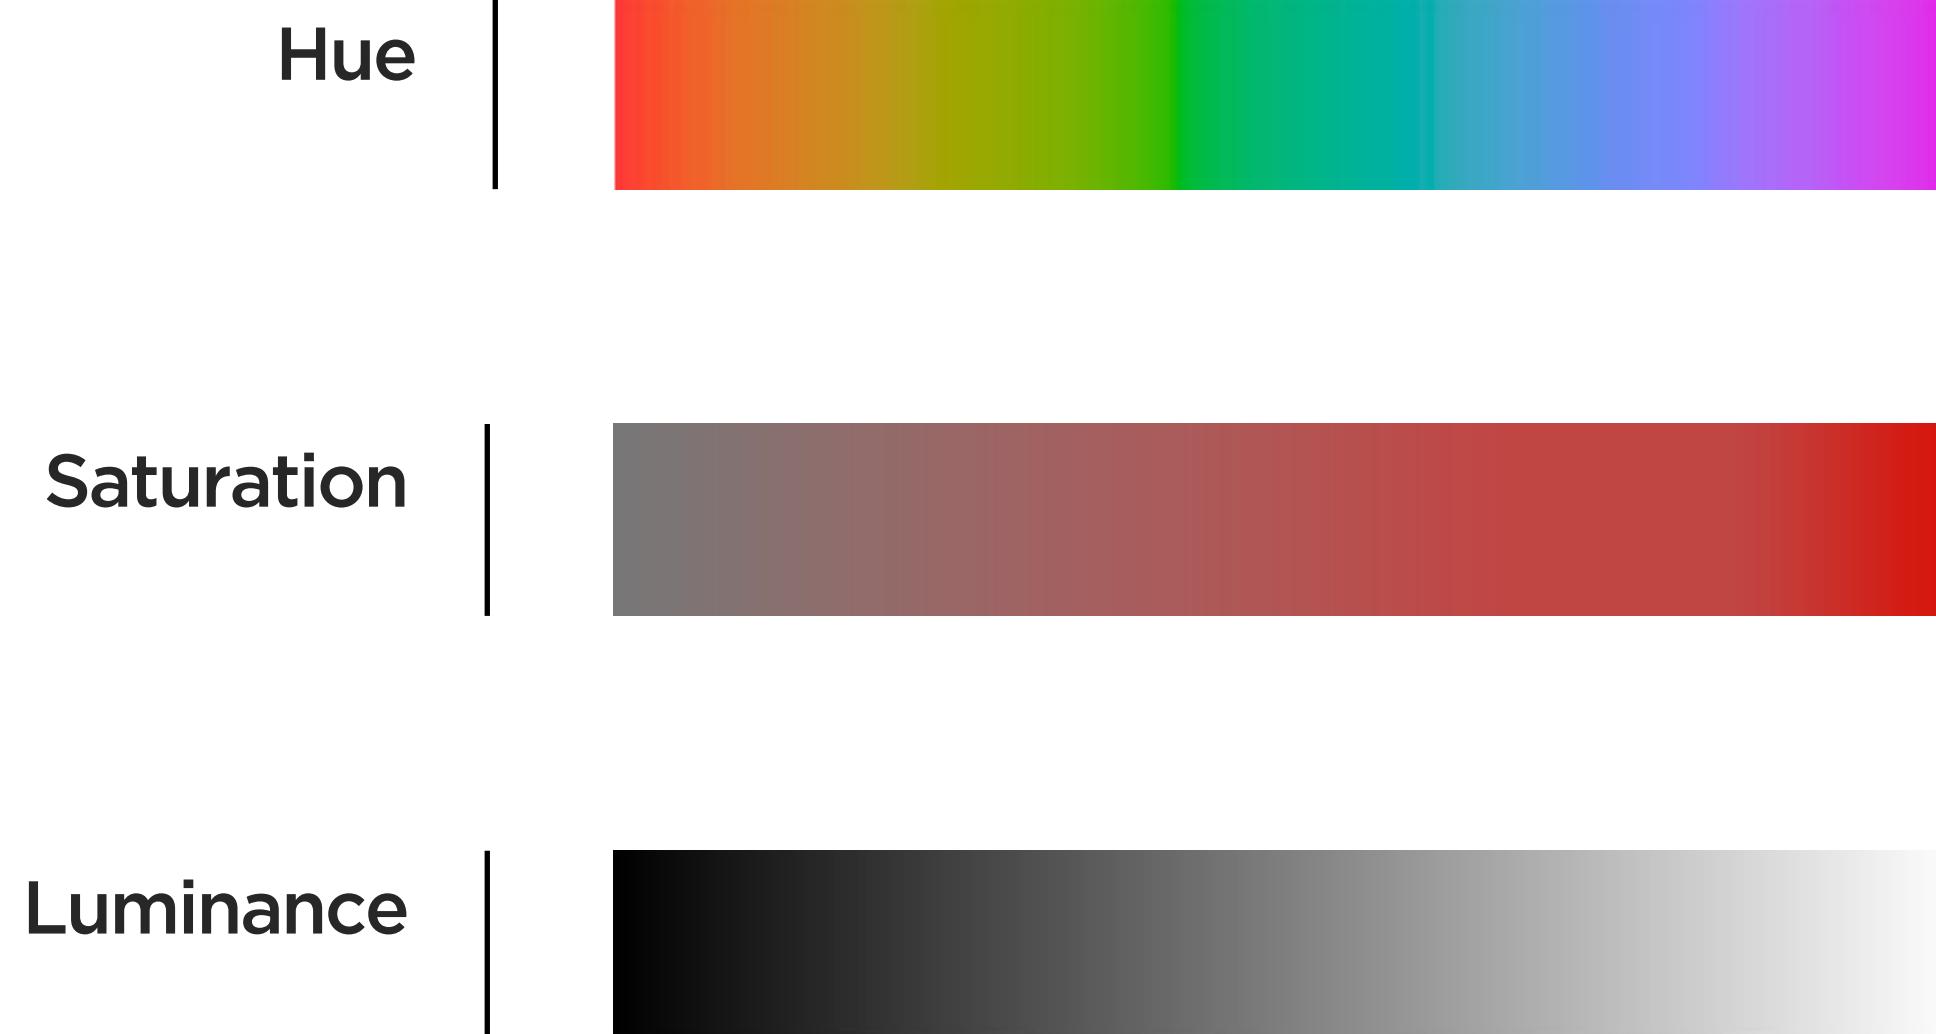

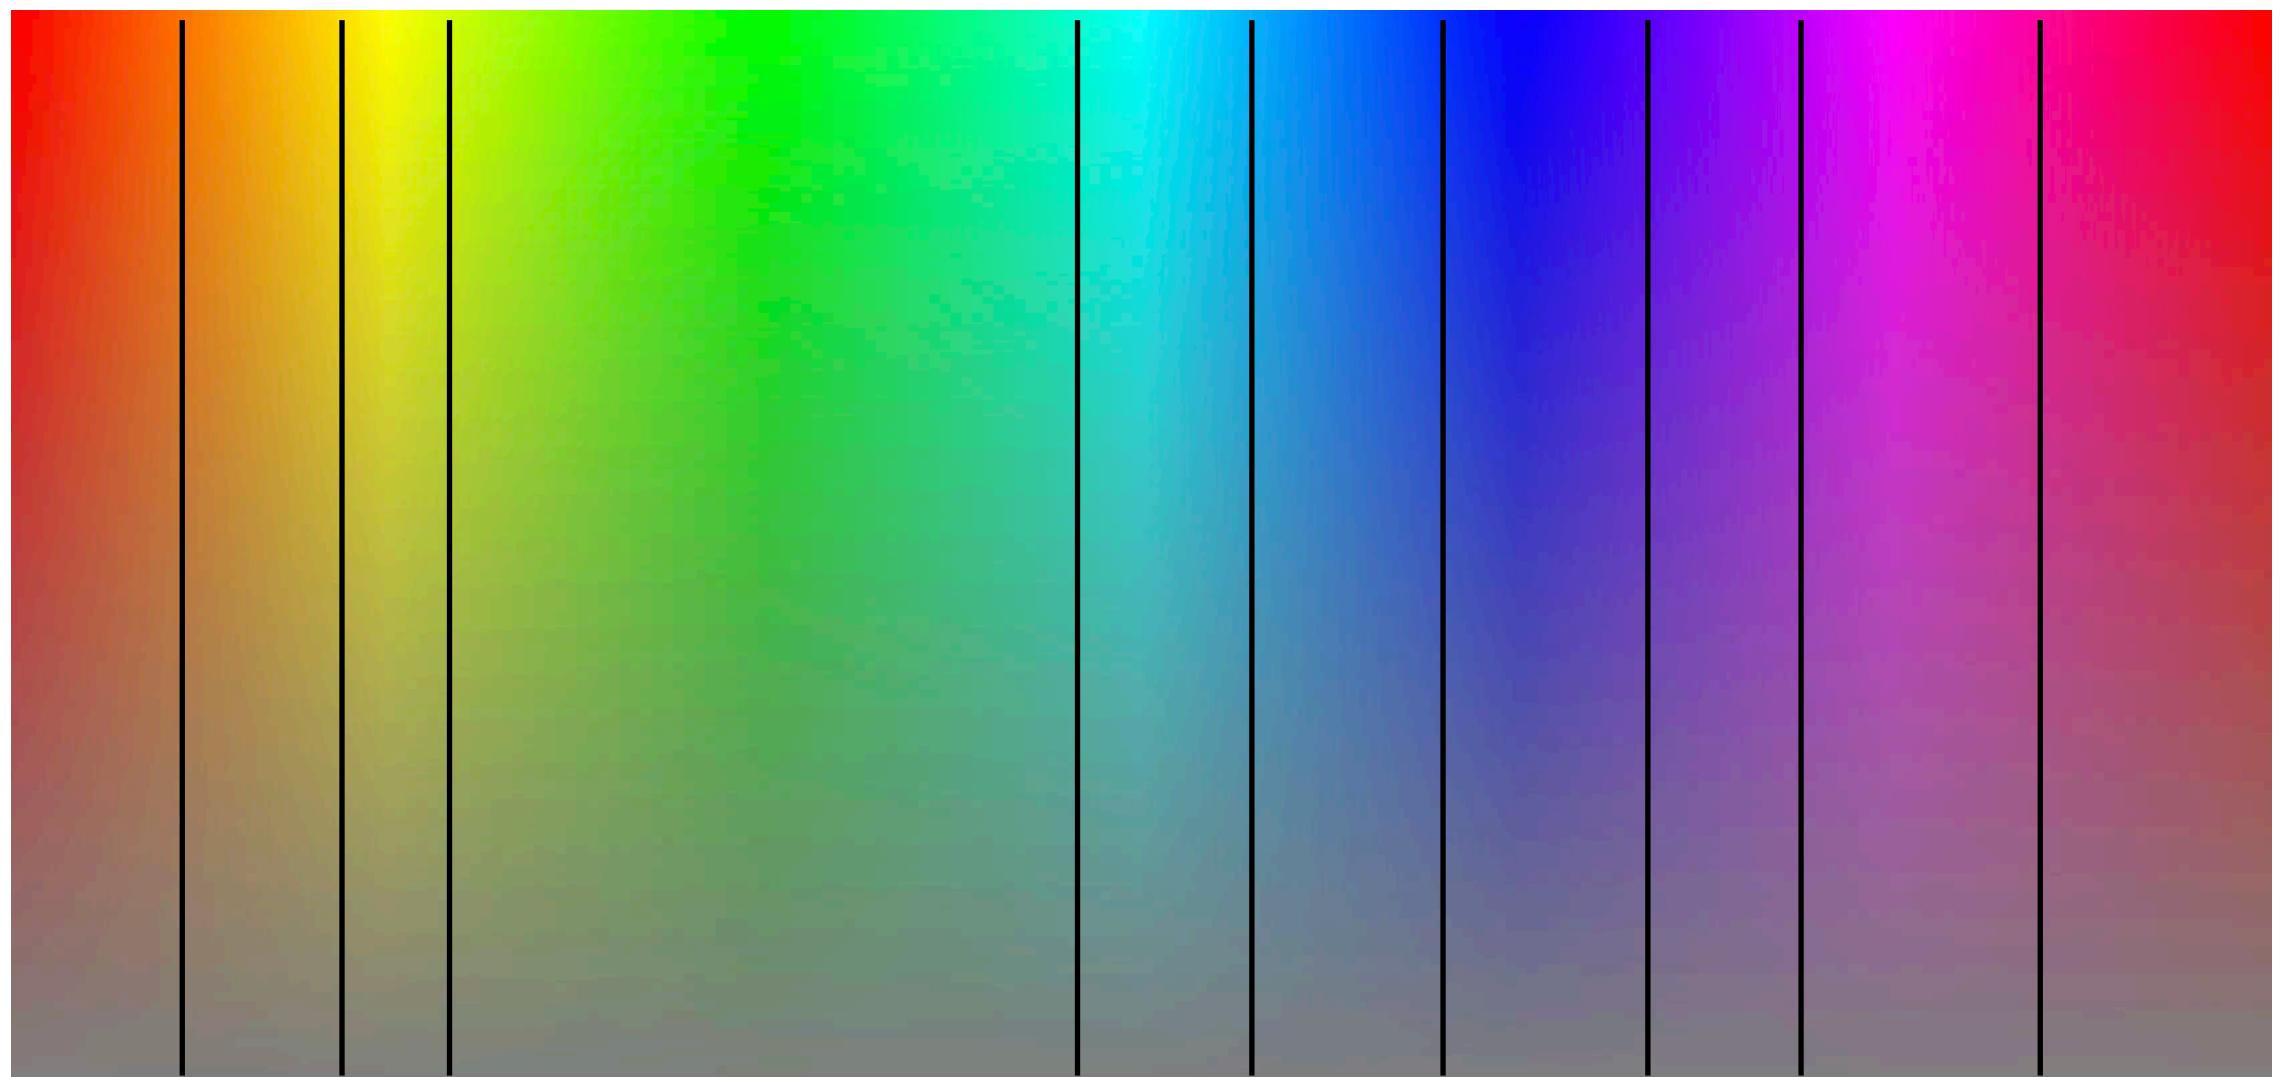

## **Implications of human perception**

## We can represent color using *color spaces*, which are mathematical models.

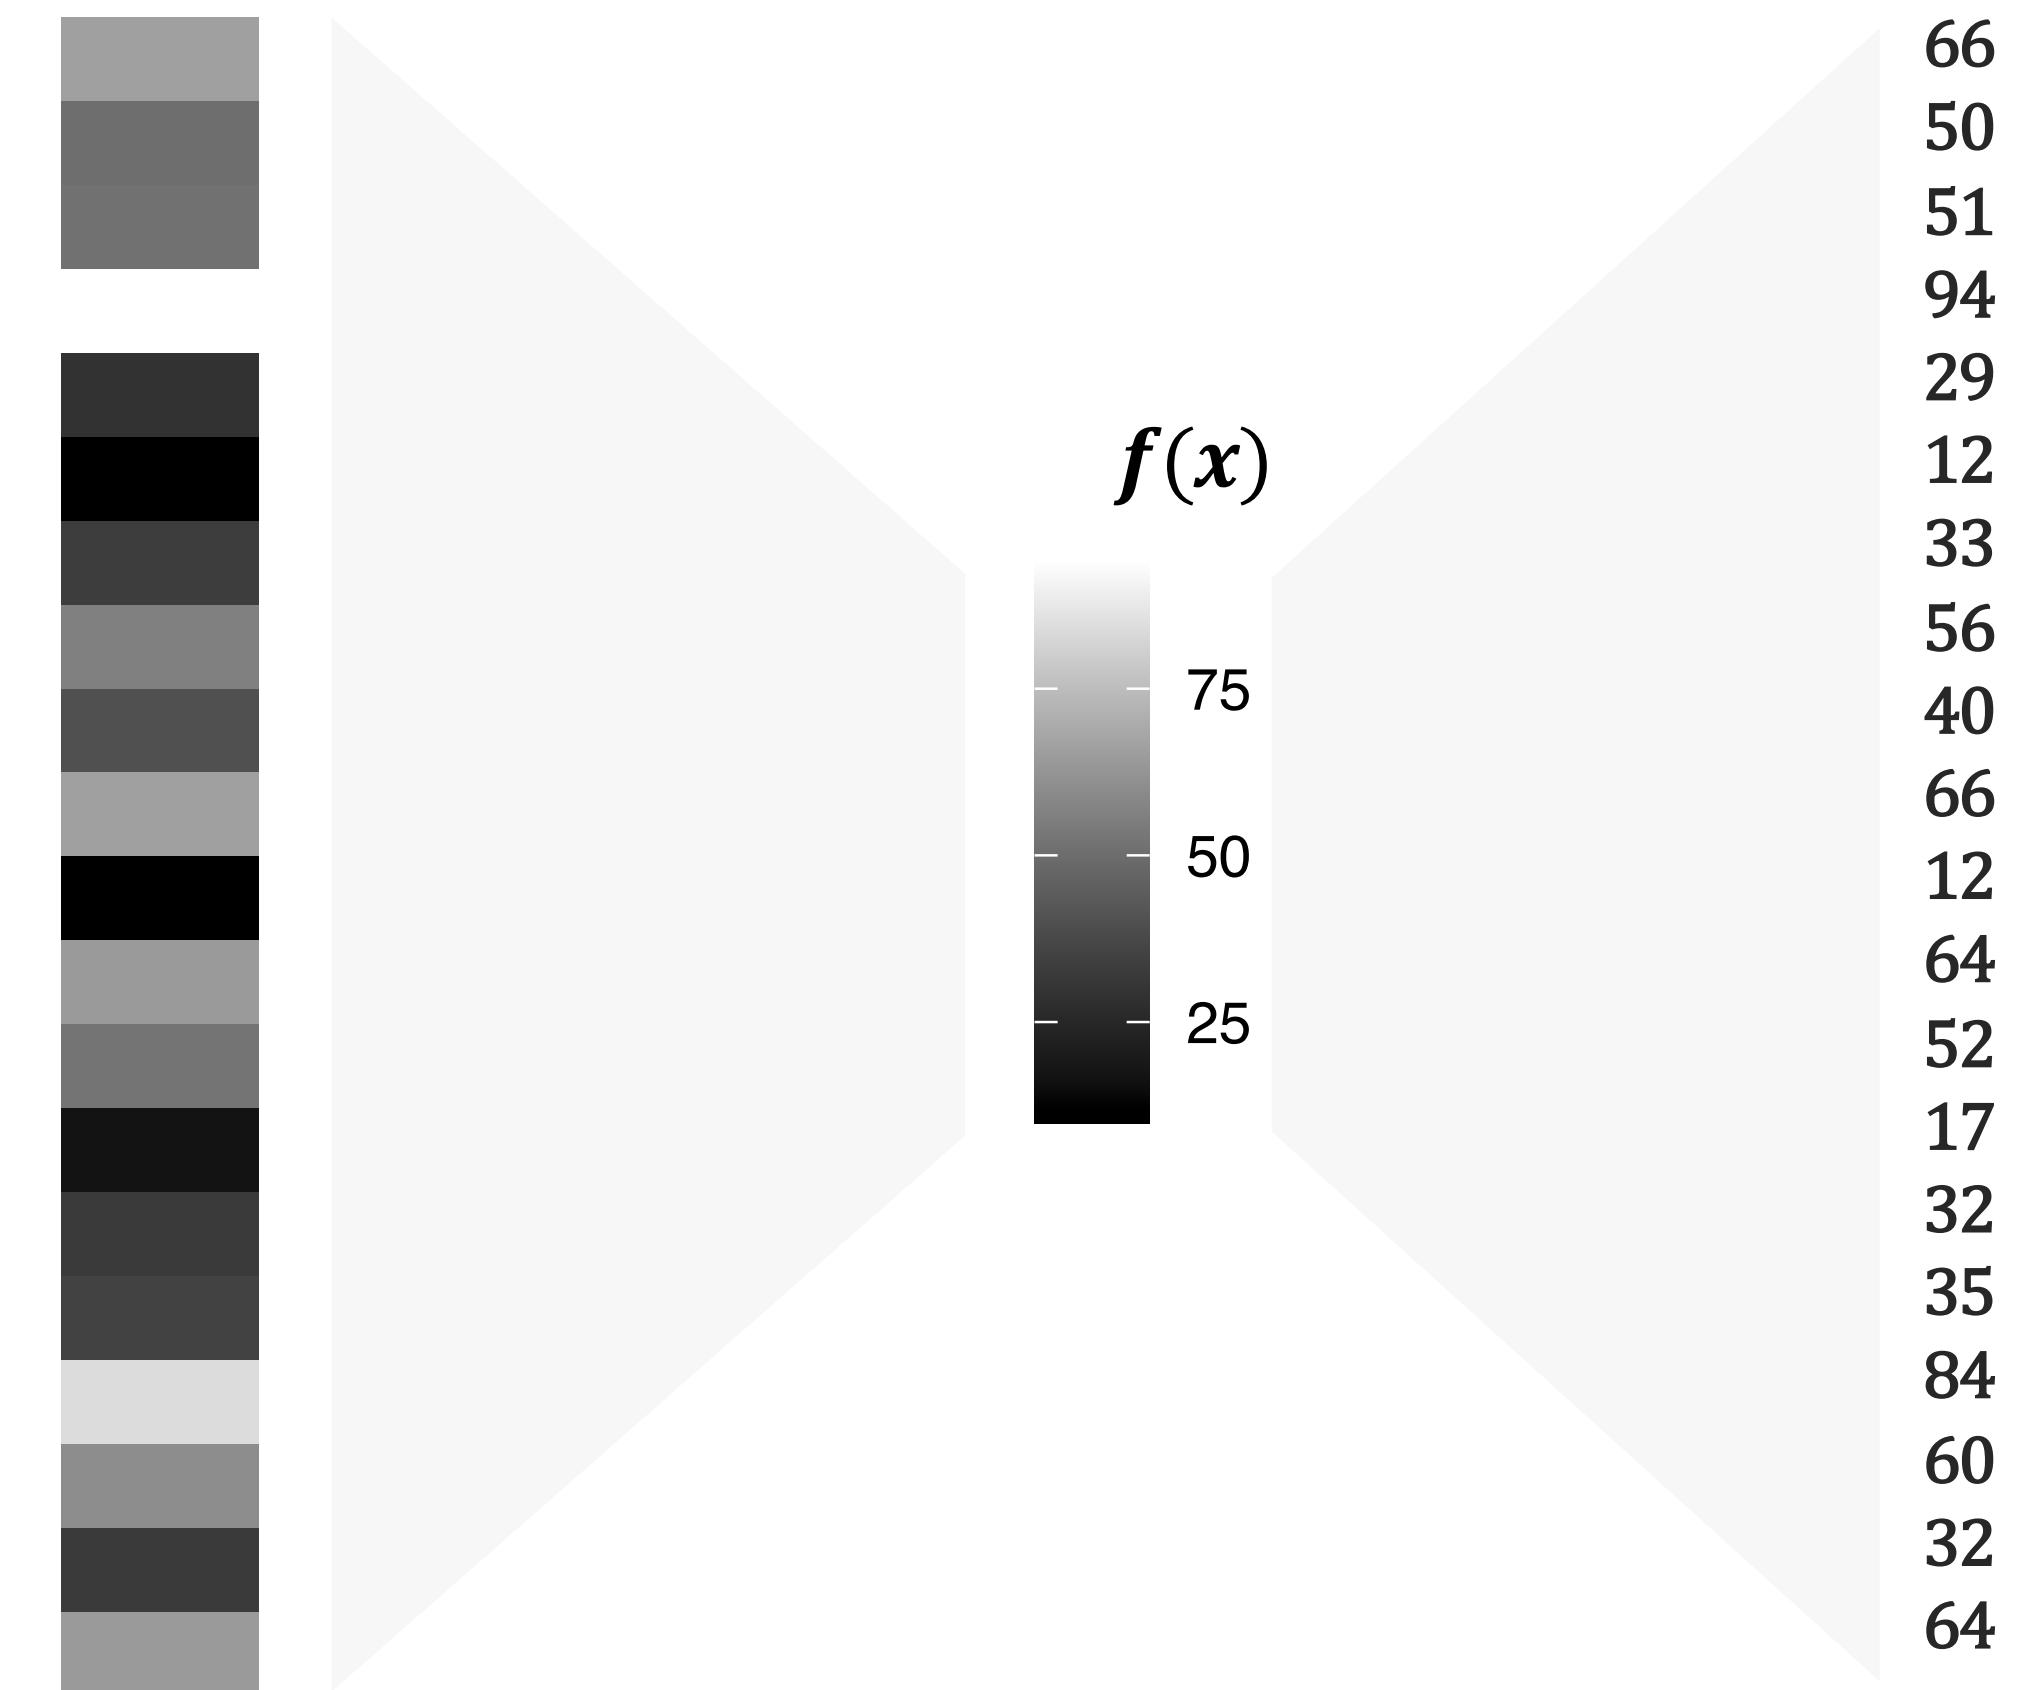

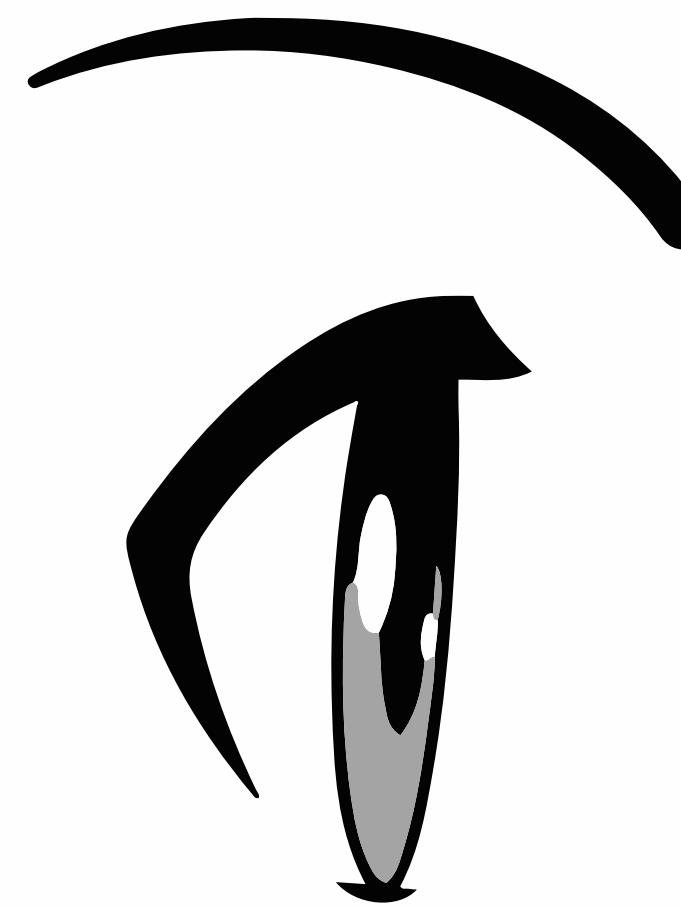

The common color model **RGB** has three dimensions — red, green, and blue — where those hues are mixed to produce a specific color. When defining colors in these dimensions, one has to know the sequence of colors in the color spectrum, e.g. mixing pure red and green makes yellow.

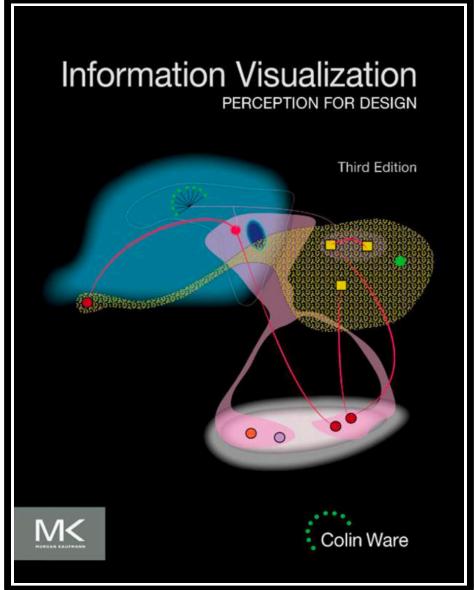

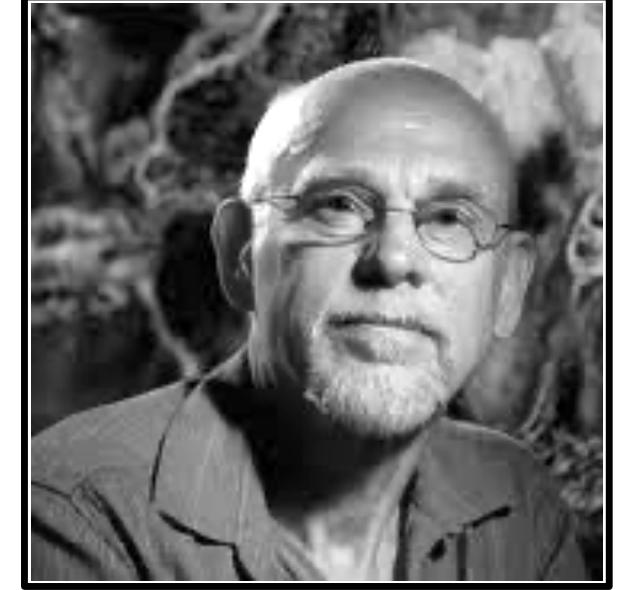

**HSL** is another color space that has mapped the same RGB color space into the alternate dimensions of hue, saturation, and luminance.

Notice this color space — shown below — has **uneven distances** between colors, **and** what we perceive as **brightness** is also uneven from left to right.

How can we compare data as a function  
of light, whether using its hue, saturation,  
or luminance?

# Information Visualization perception for design

*Ware*

Bio

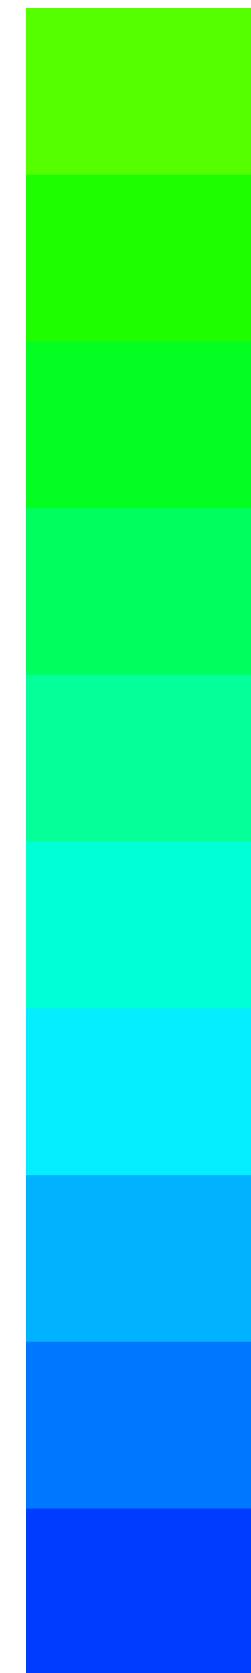

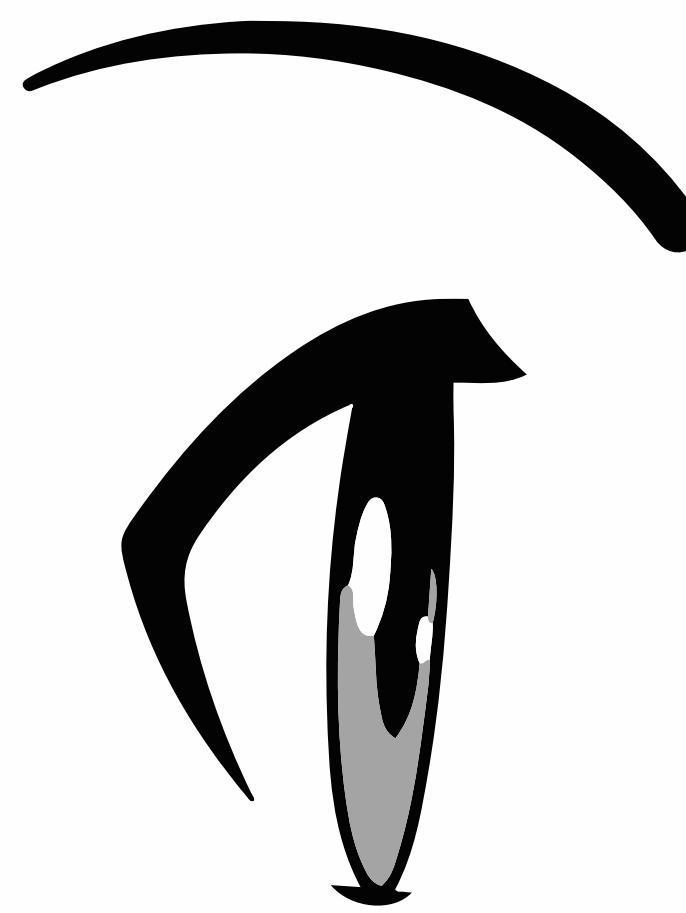

**TODO: develop this section**

**Brightness perception is a nonlinear function of luminance.**

Perceived brightness is a very nonlinear function of the amount of light emitted. That function follows the power law:

$$\text{Perceived brightness} = \text{Luminance}^n$$

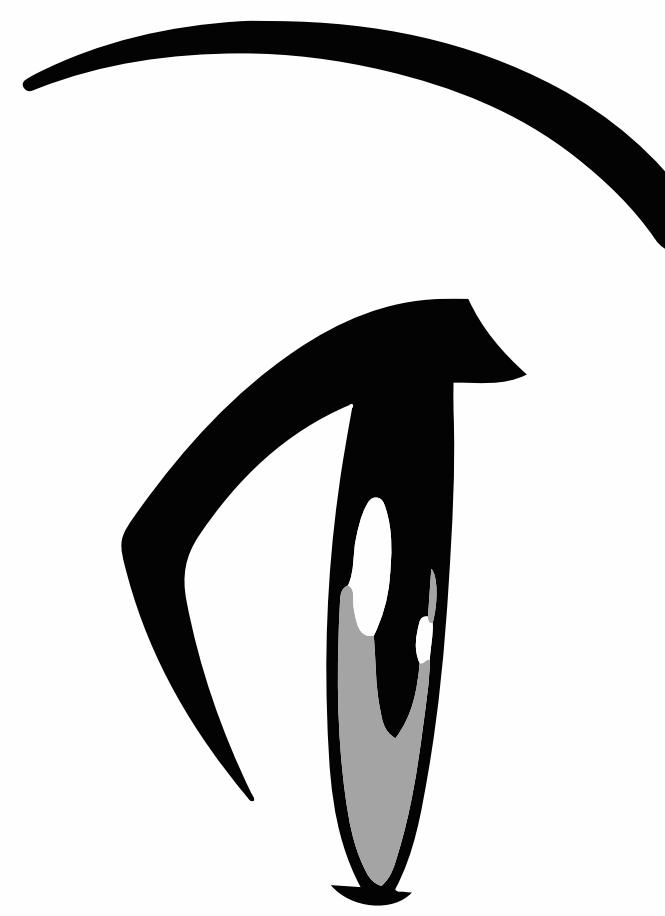

Where the value of  $n$  depends on the size of the patch of light. For circular patches of light subtending 5 degrees of visual angle,  $n$  is 0.333, whereas for point sources of light  $n$  is close to 0.5.

## Changing the hue values in the sRGB color space from green to blue in 10 equal steps fails to uniformly scale.

The green colors look almost identical, while the blue colors are more diverse. It also has a lot of variation in the lightness of the colors, with the cyan colors in the middle looking brighter than the blue colors.

This happens because the default sRGB color space (and any color model built on it like HSV and HSL) is irregular, which means that **even though the rectangles have evenly spaced hue values, the corresponding effect is not linear to the human eye.**

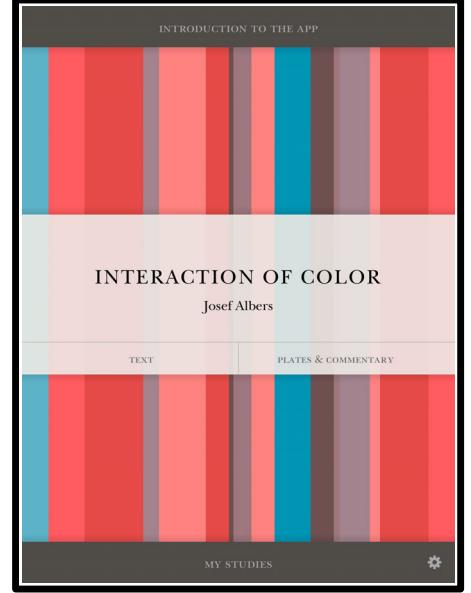

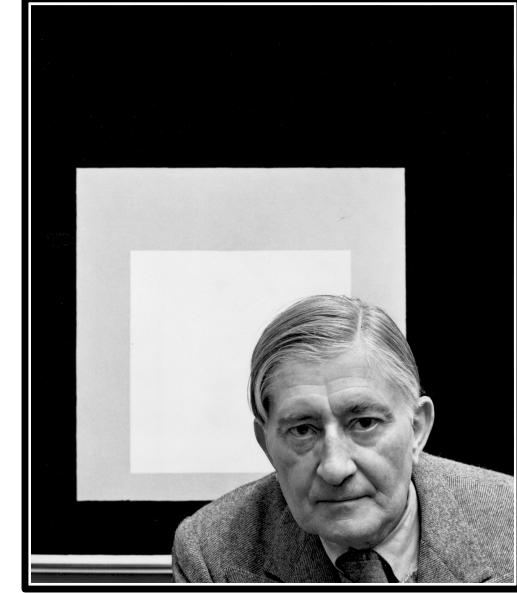

## But other color spaces are *perceptually uniform*, better for representing data.

Humans compute color signals from our retina cones via an opponent process model, which makes it impossible to see reddish-green or yellowish-blue colors.

The International Commission on Illumination (CIE) studied human perception and re-mapped color so that we perceive color changes uniformly. Their **CIELUV** color model has two dimensions — u and v — that represent color scales from red to green and yellow to blue. To create a color in the CIELUV color space, one has to define the lightness of the color (l), whether it is reddish or greenish (u), and whether it is yellowish or bluish (v).

More modern implementations, like **HSLuv** improve upon this work by mapping colors as perceived into the familiar and intuitive HSL dimensions. **To the left**, our green-to-blue hues in 10 equal steps using the HSLuv model are perceptually uniform.

# Interaction of Color

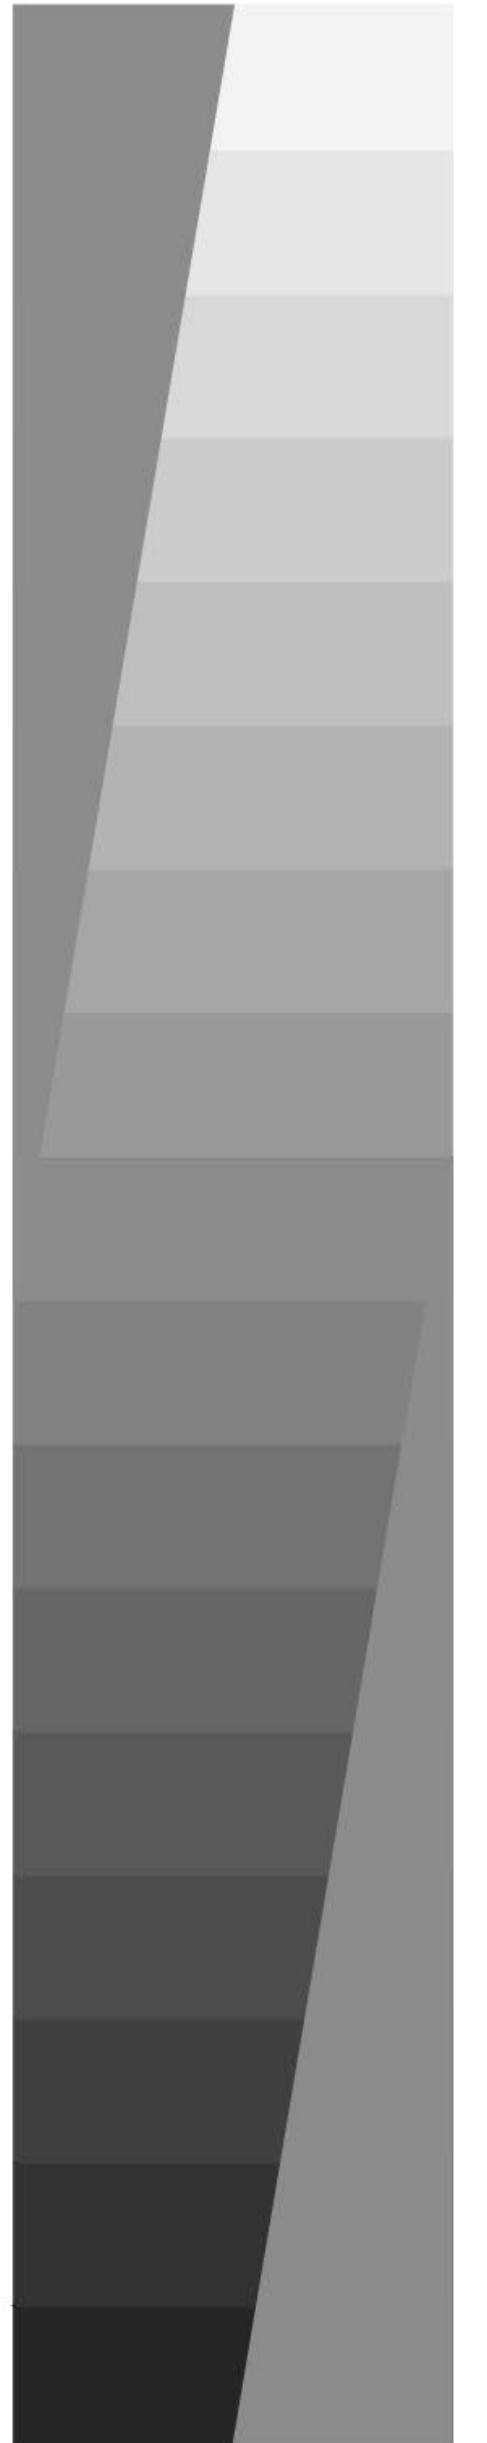

Albers

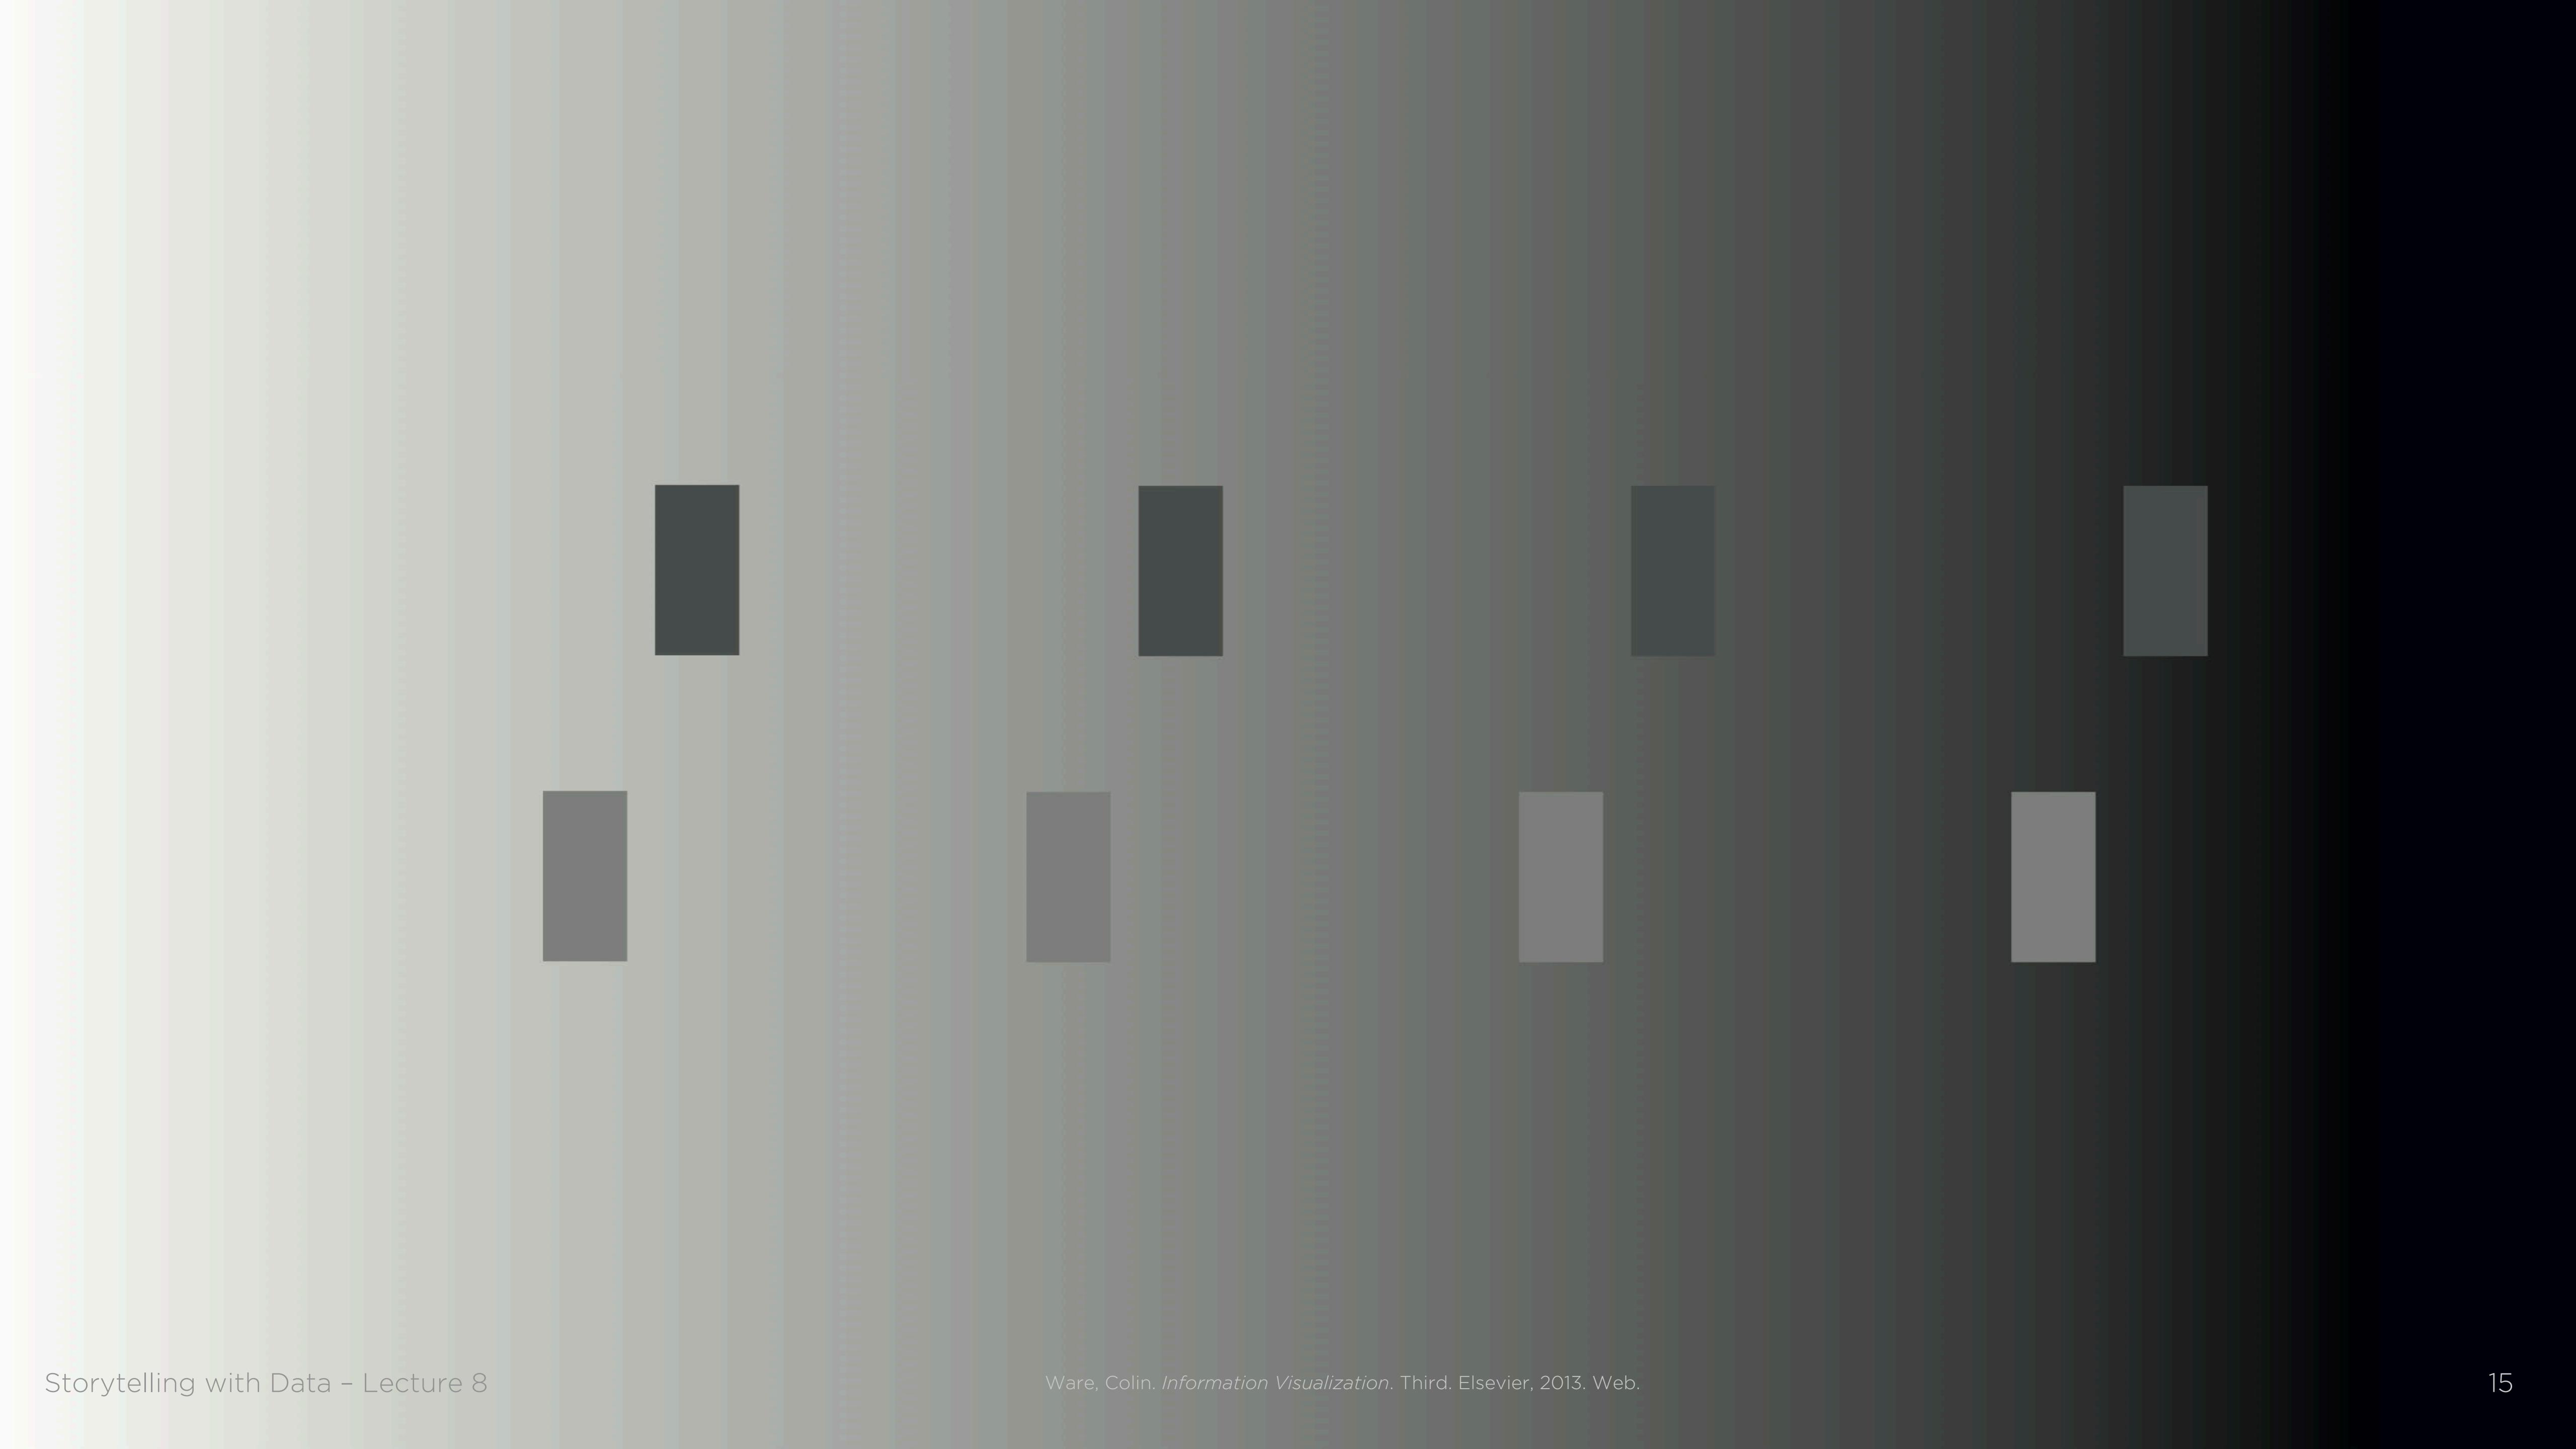

Bio

## Color is relative

In visual perception a color is almost never seen as it really is — as it physically is. This fact makes color the most relative medium in art.

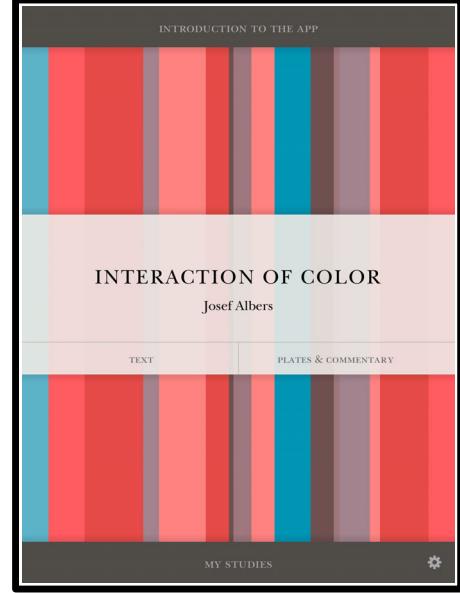

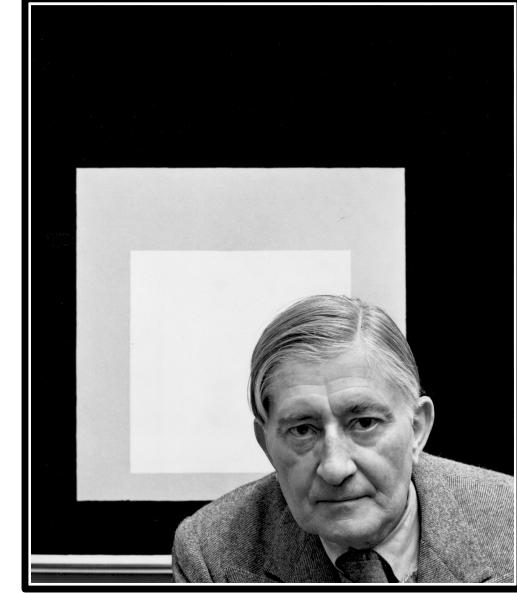

**TODO: develop this section**

# Names of color

**TODO: develop this section**

# Interaction of Color

Albers

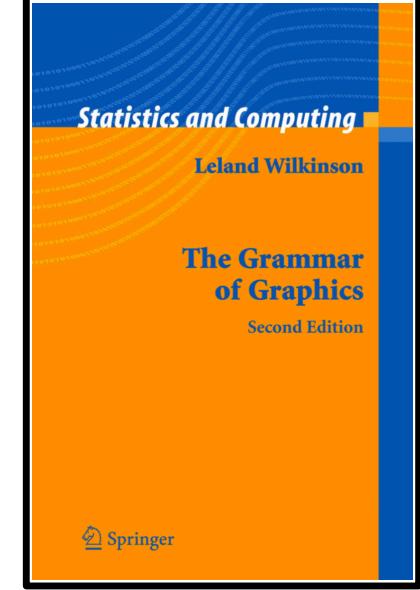

Bio

Each of us  
imagines a color  
from its name  
differently

If one says “red” (the name of a color) and there are 50 people listening, it can be expected that there will be 50 reds in their minds. And one can be sure that all these reds will be very different.

# Graphics have a grammar

# The grammar of graphics

## Wilkinson

Leland, formerly VP of Statistics at Tableau, is a statistician and computer scientist at H2O.ai, and Adjunct Professor of Computer Science at University of Illinois at Chicago. His research focuses on scientific visualization and statistical graphics.

A grammar links visual perception to graphics

Theory of graphics, not chart typology

Charts are just instances of more general objects

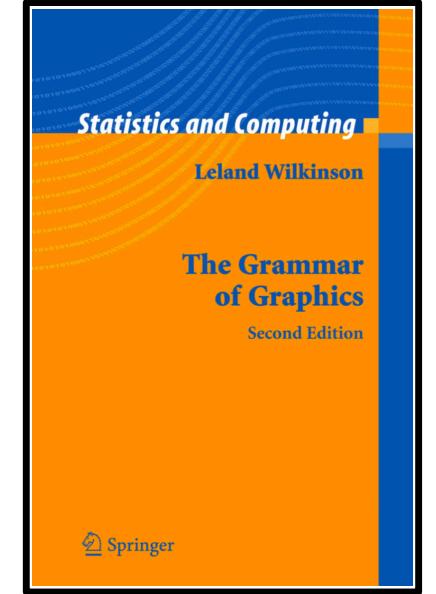

Thinking in terms of charts limit re-use for new, different cases

Once we understand how our audience can best perceive our data comparisons, a grammar helps us build graphics to accomplish that goal.

We often call graphics charts ... pie charts, bar charts, line charts, and so on. But **Customary usage and standards can blind us to the diversity of the graphics domain**; a formal system can liberate us from conventional restrictions.

Charts are usually instances of much more general objects. Once we understand that a pie is a divided bar in polar coordinates, we can construct other polar graphics that are less well known. We will also come to realize why a histogram is not a bar chart and why many other **graphics that look similar nevertheless have different grammars**.

If we ... develop charting instead of a graphing: **we inevitably will offer fewer charts than people want**. And we will have no way to add new charts ... without generating complex new code.

# The grammar of graphics

## Wilkinson

Leland, formerly VP of Statistics at Tableau, is a statistician and computer scientist at H2O.ai, and Adjunct Professor of Computer Science at University of Illinois at Chicago. His research focuses on scientific visualization and statistical graphics.

### So what's a graph, and a graphic?

A **graph** is a set of points. A mathematical graph cannot be seen. It is an abstraction. A **graphic, however, is a physical representation of a graph**. This representation is accomplished by realizing graphs with aesthetic attributes such as size or color.

### Six components to statistical graphs

**Algebra** the operations that allow us to combine variables, specify graph dimensions

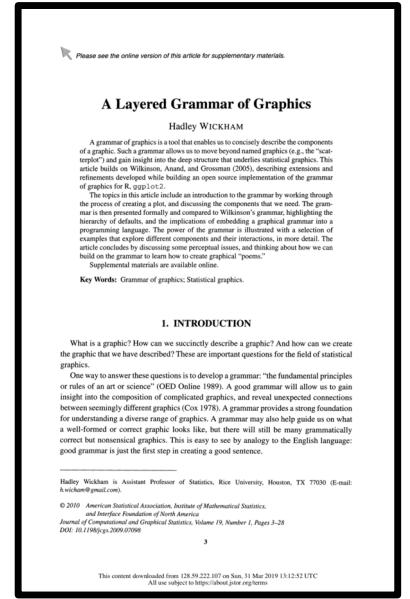

**Scales** the representation of variables on measured dimensions (e.g., linear, log)

**Statistics** the functions that allow graphs to change their appearance and representation

**Geometry** the creation of geometric graphs from variables

**Coordinates** coordinate systems, from polar coordinates to more complex map projections and general transformations

**Aesthetics** covers the sensory attributes used to represent graphics.

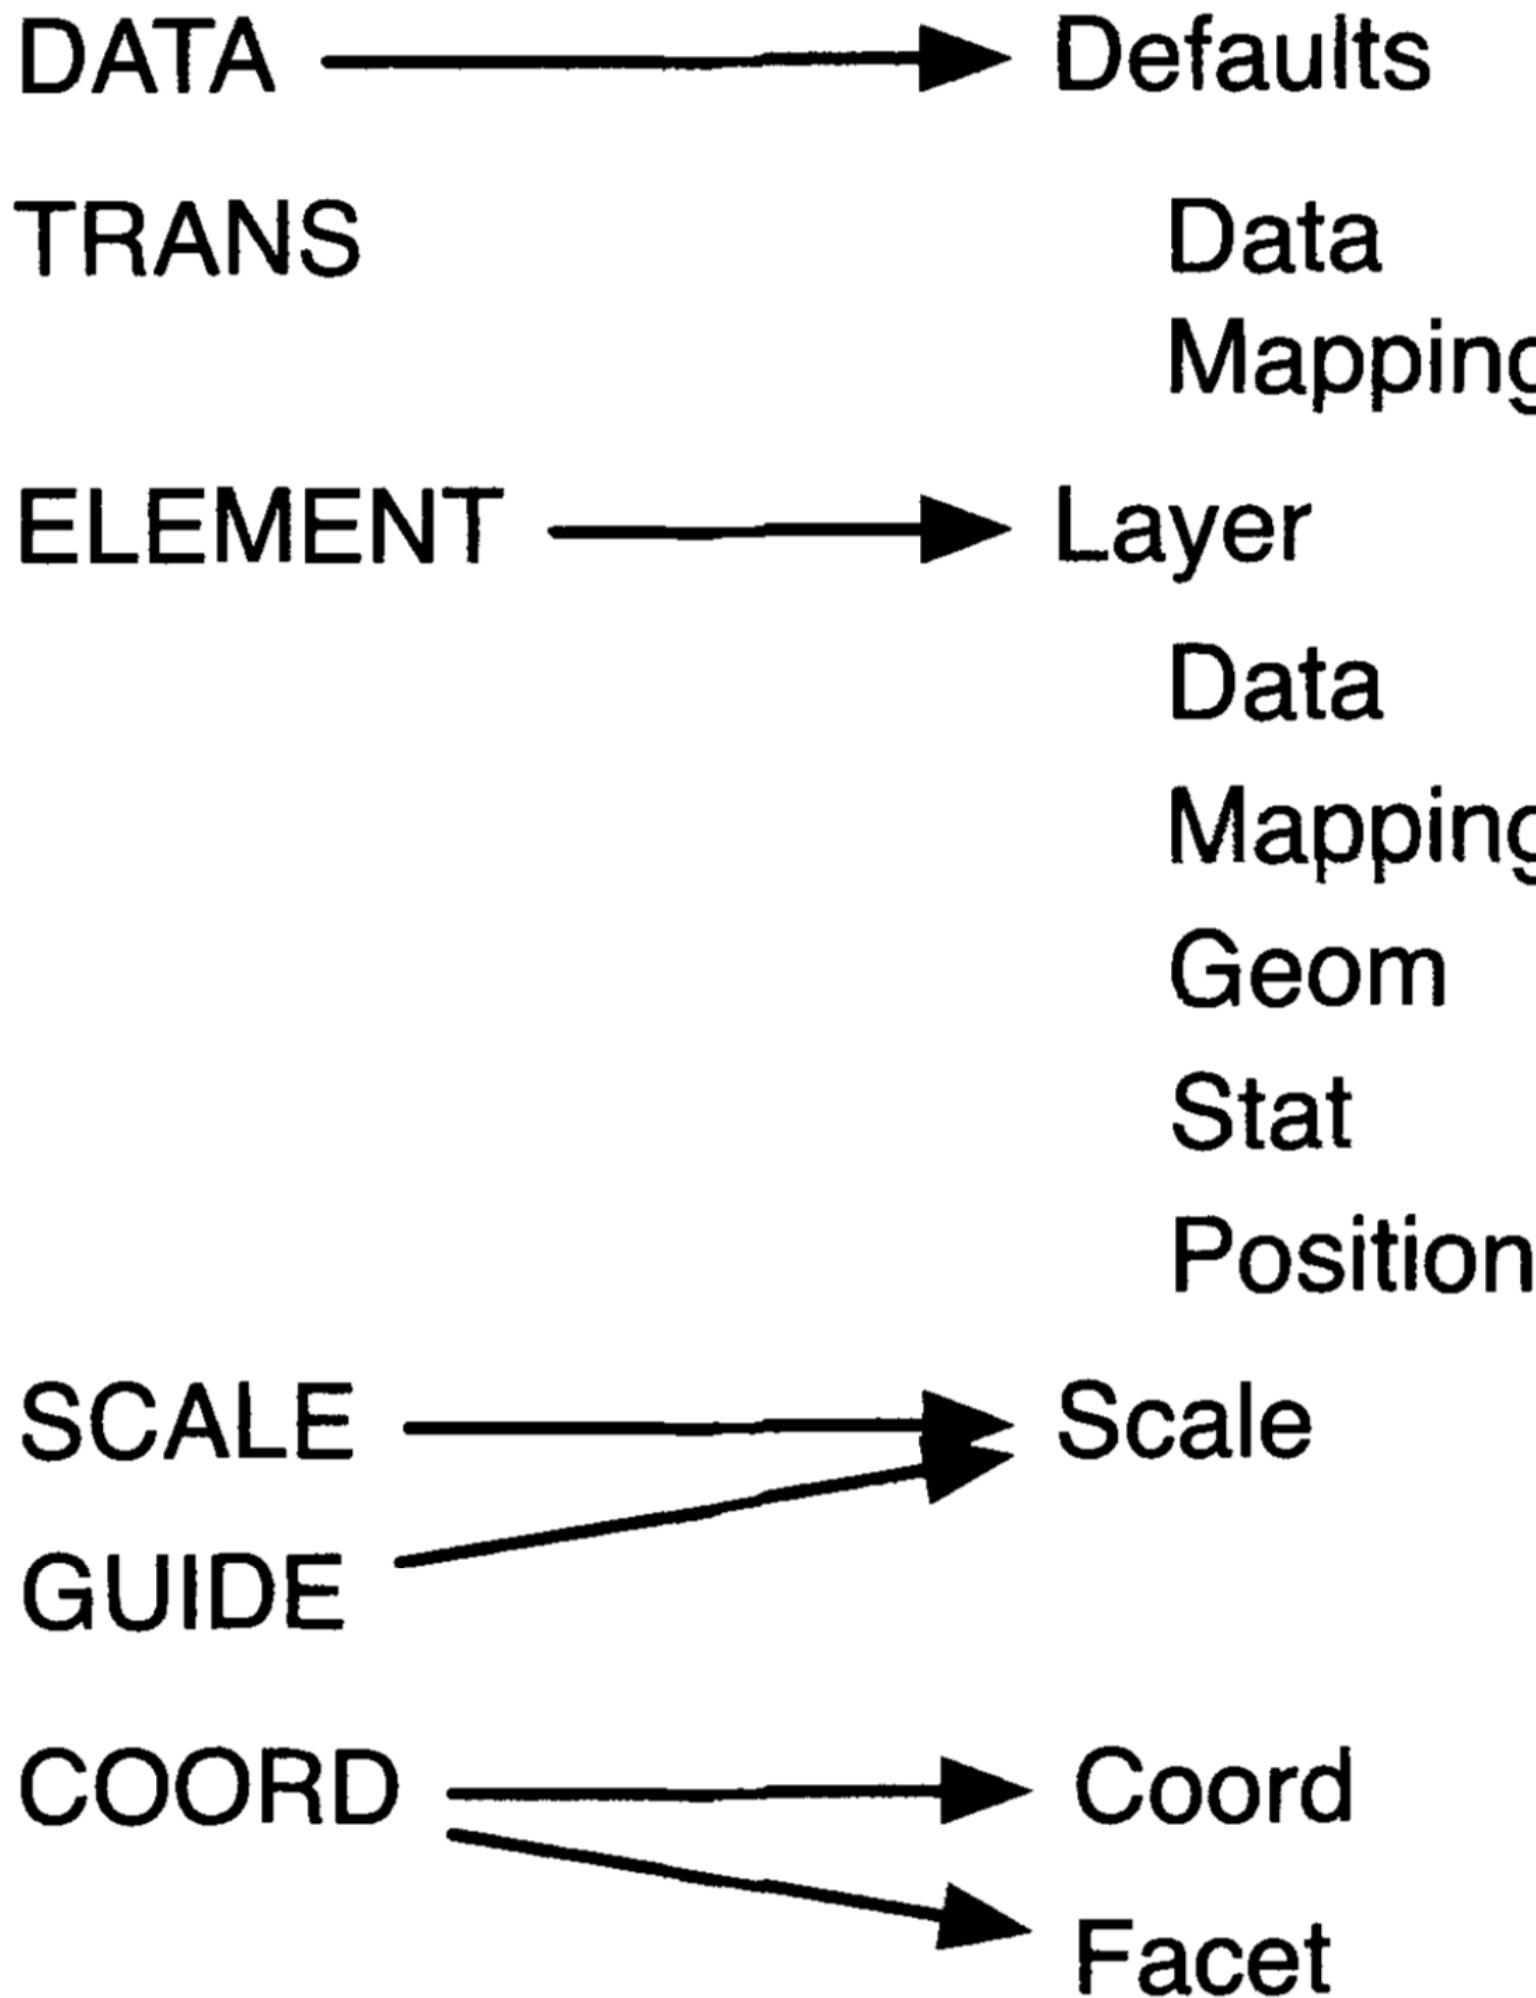

# A layered grammar of graphics

*Wickham*

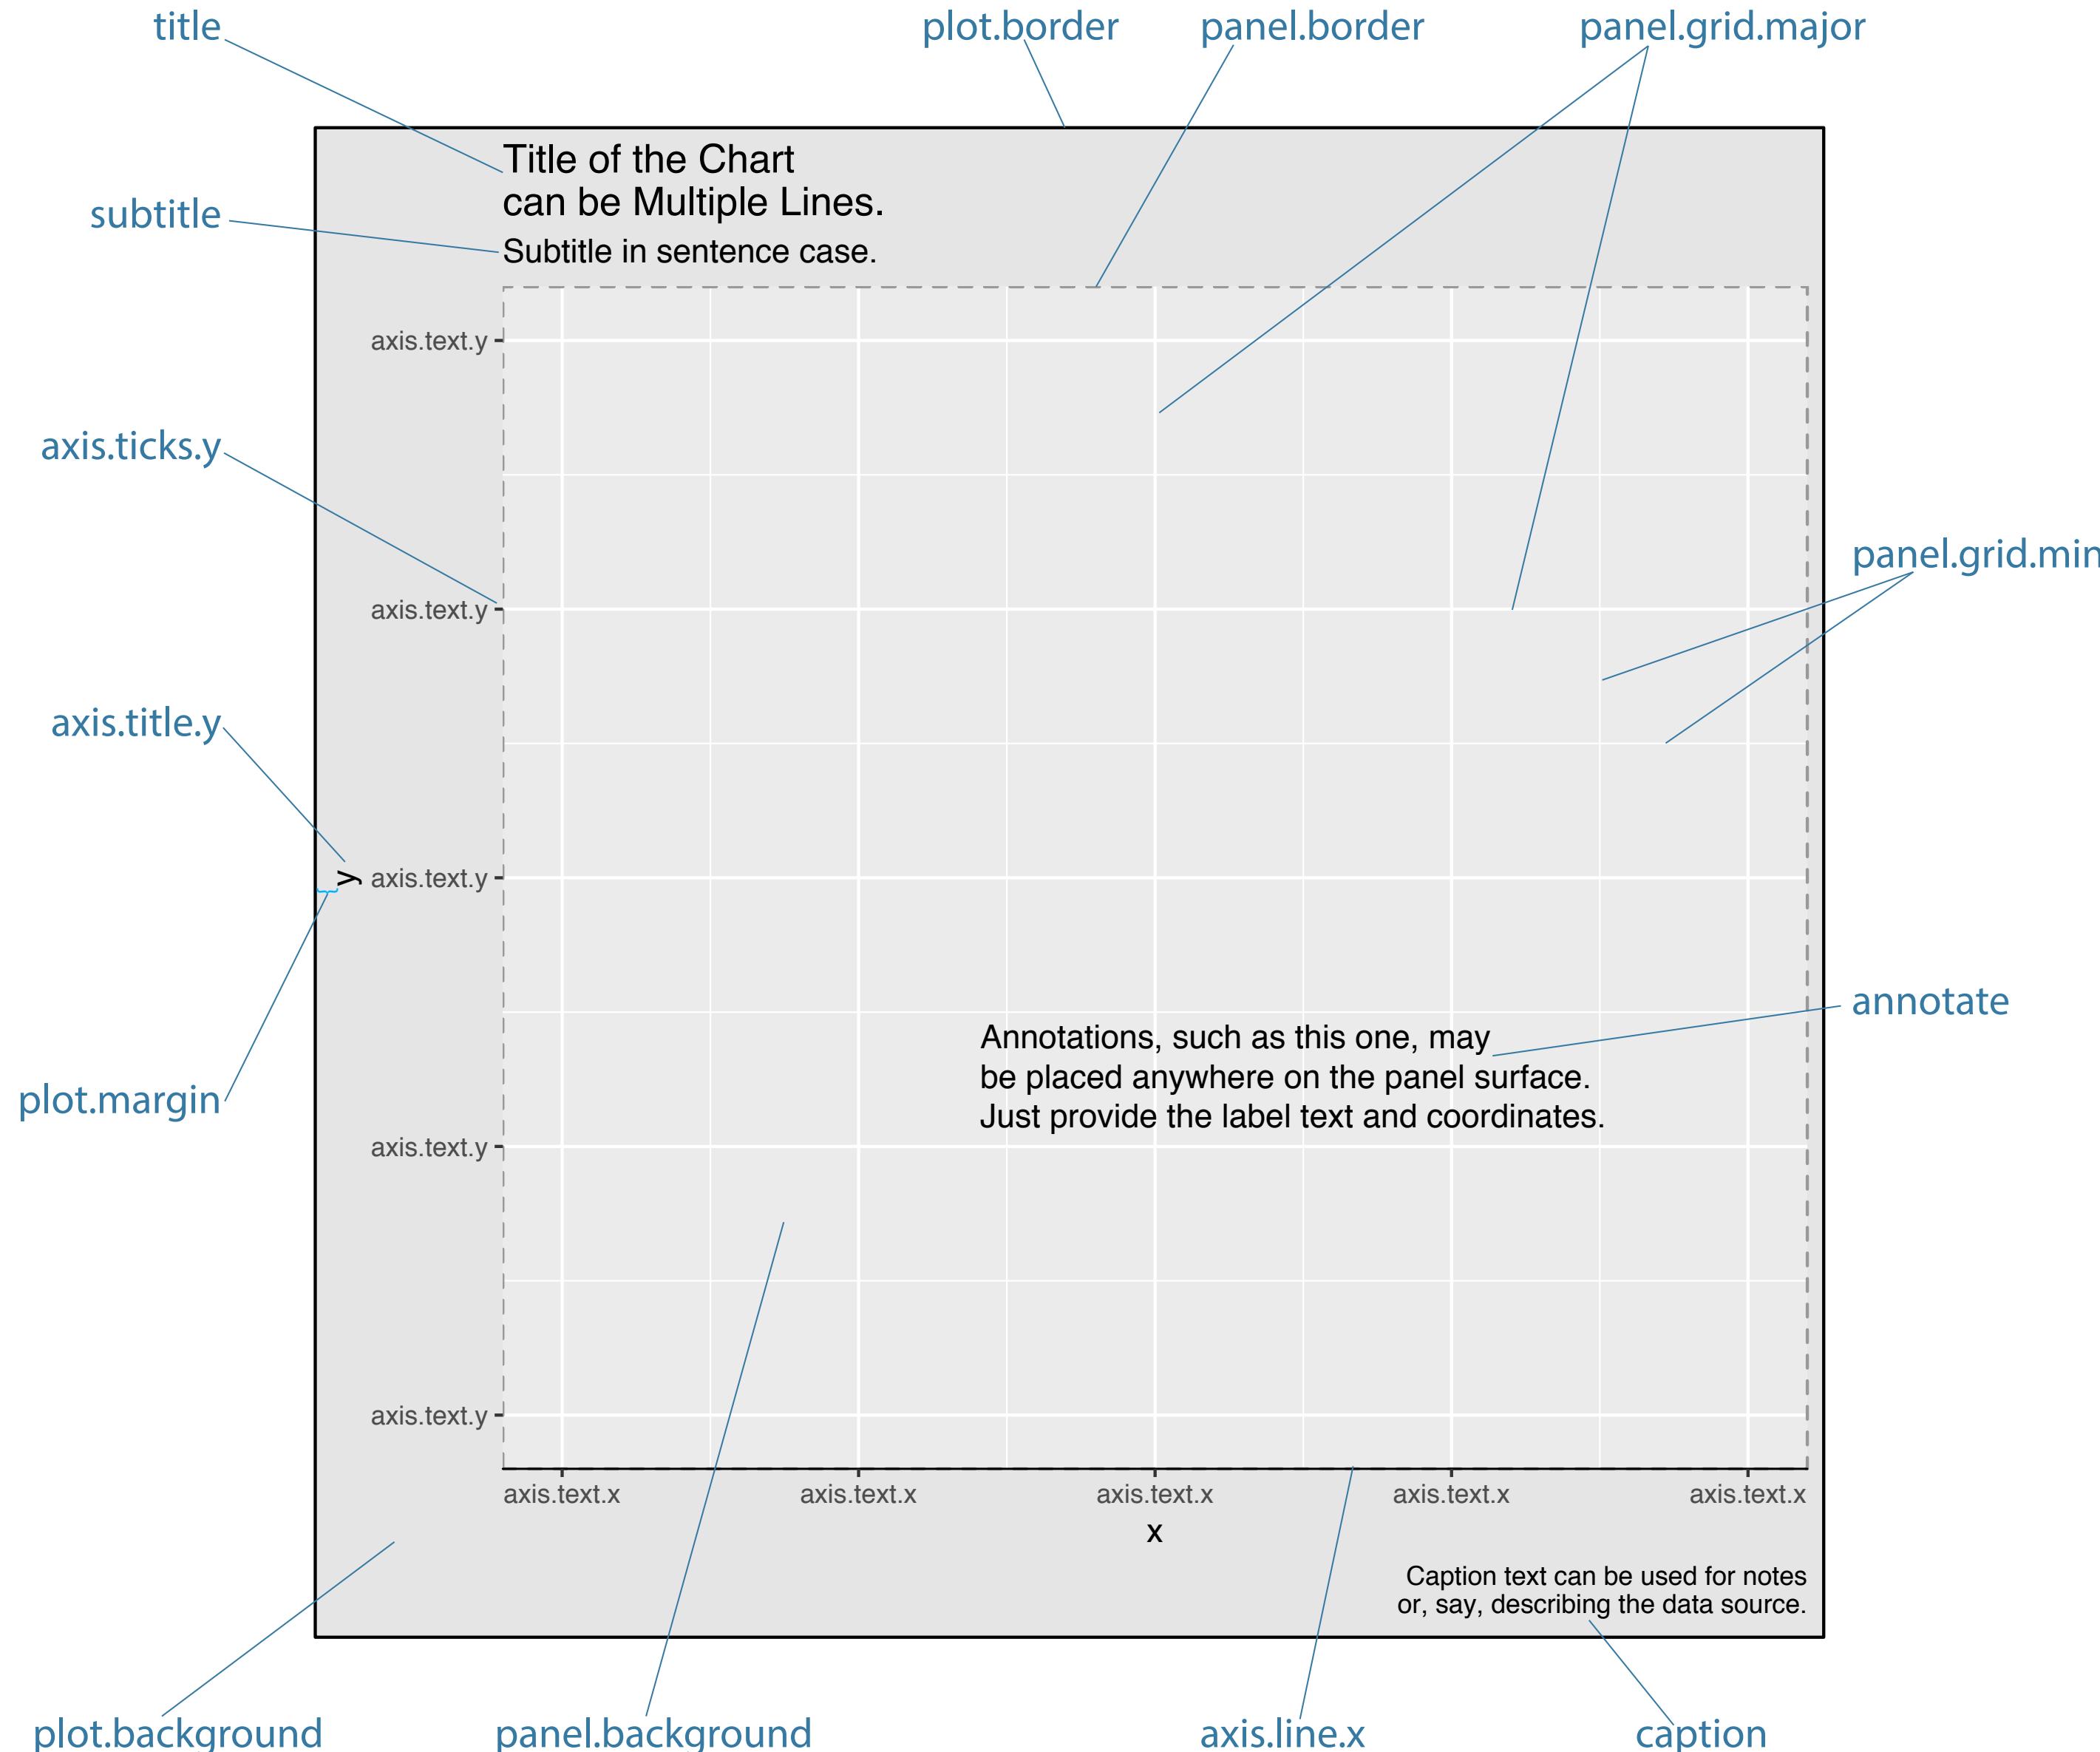

Hadley, an adjunct professor at Rice University, is the creator of the R package ggplot2, which is a limited implementation of Wilkinson's seminal work. gg is short for grammar of graphics.

Her work is part of the permanent collection of the Museum of Modern Art. She is co-founder and Design Director of Accurat, a data-driven design firm. After receiving her master's degree in Architecture, she earned her PhD in Design at Politecnico di Milano.

Create displays with layers, hierarchies

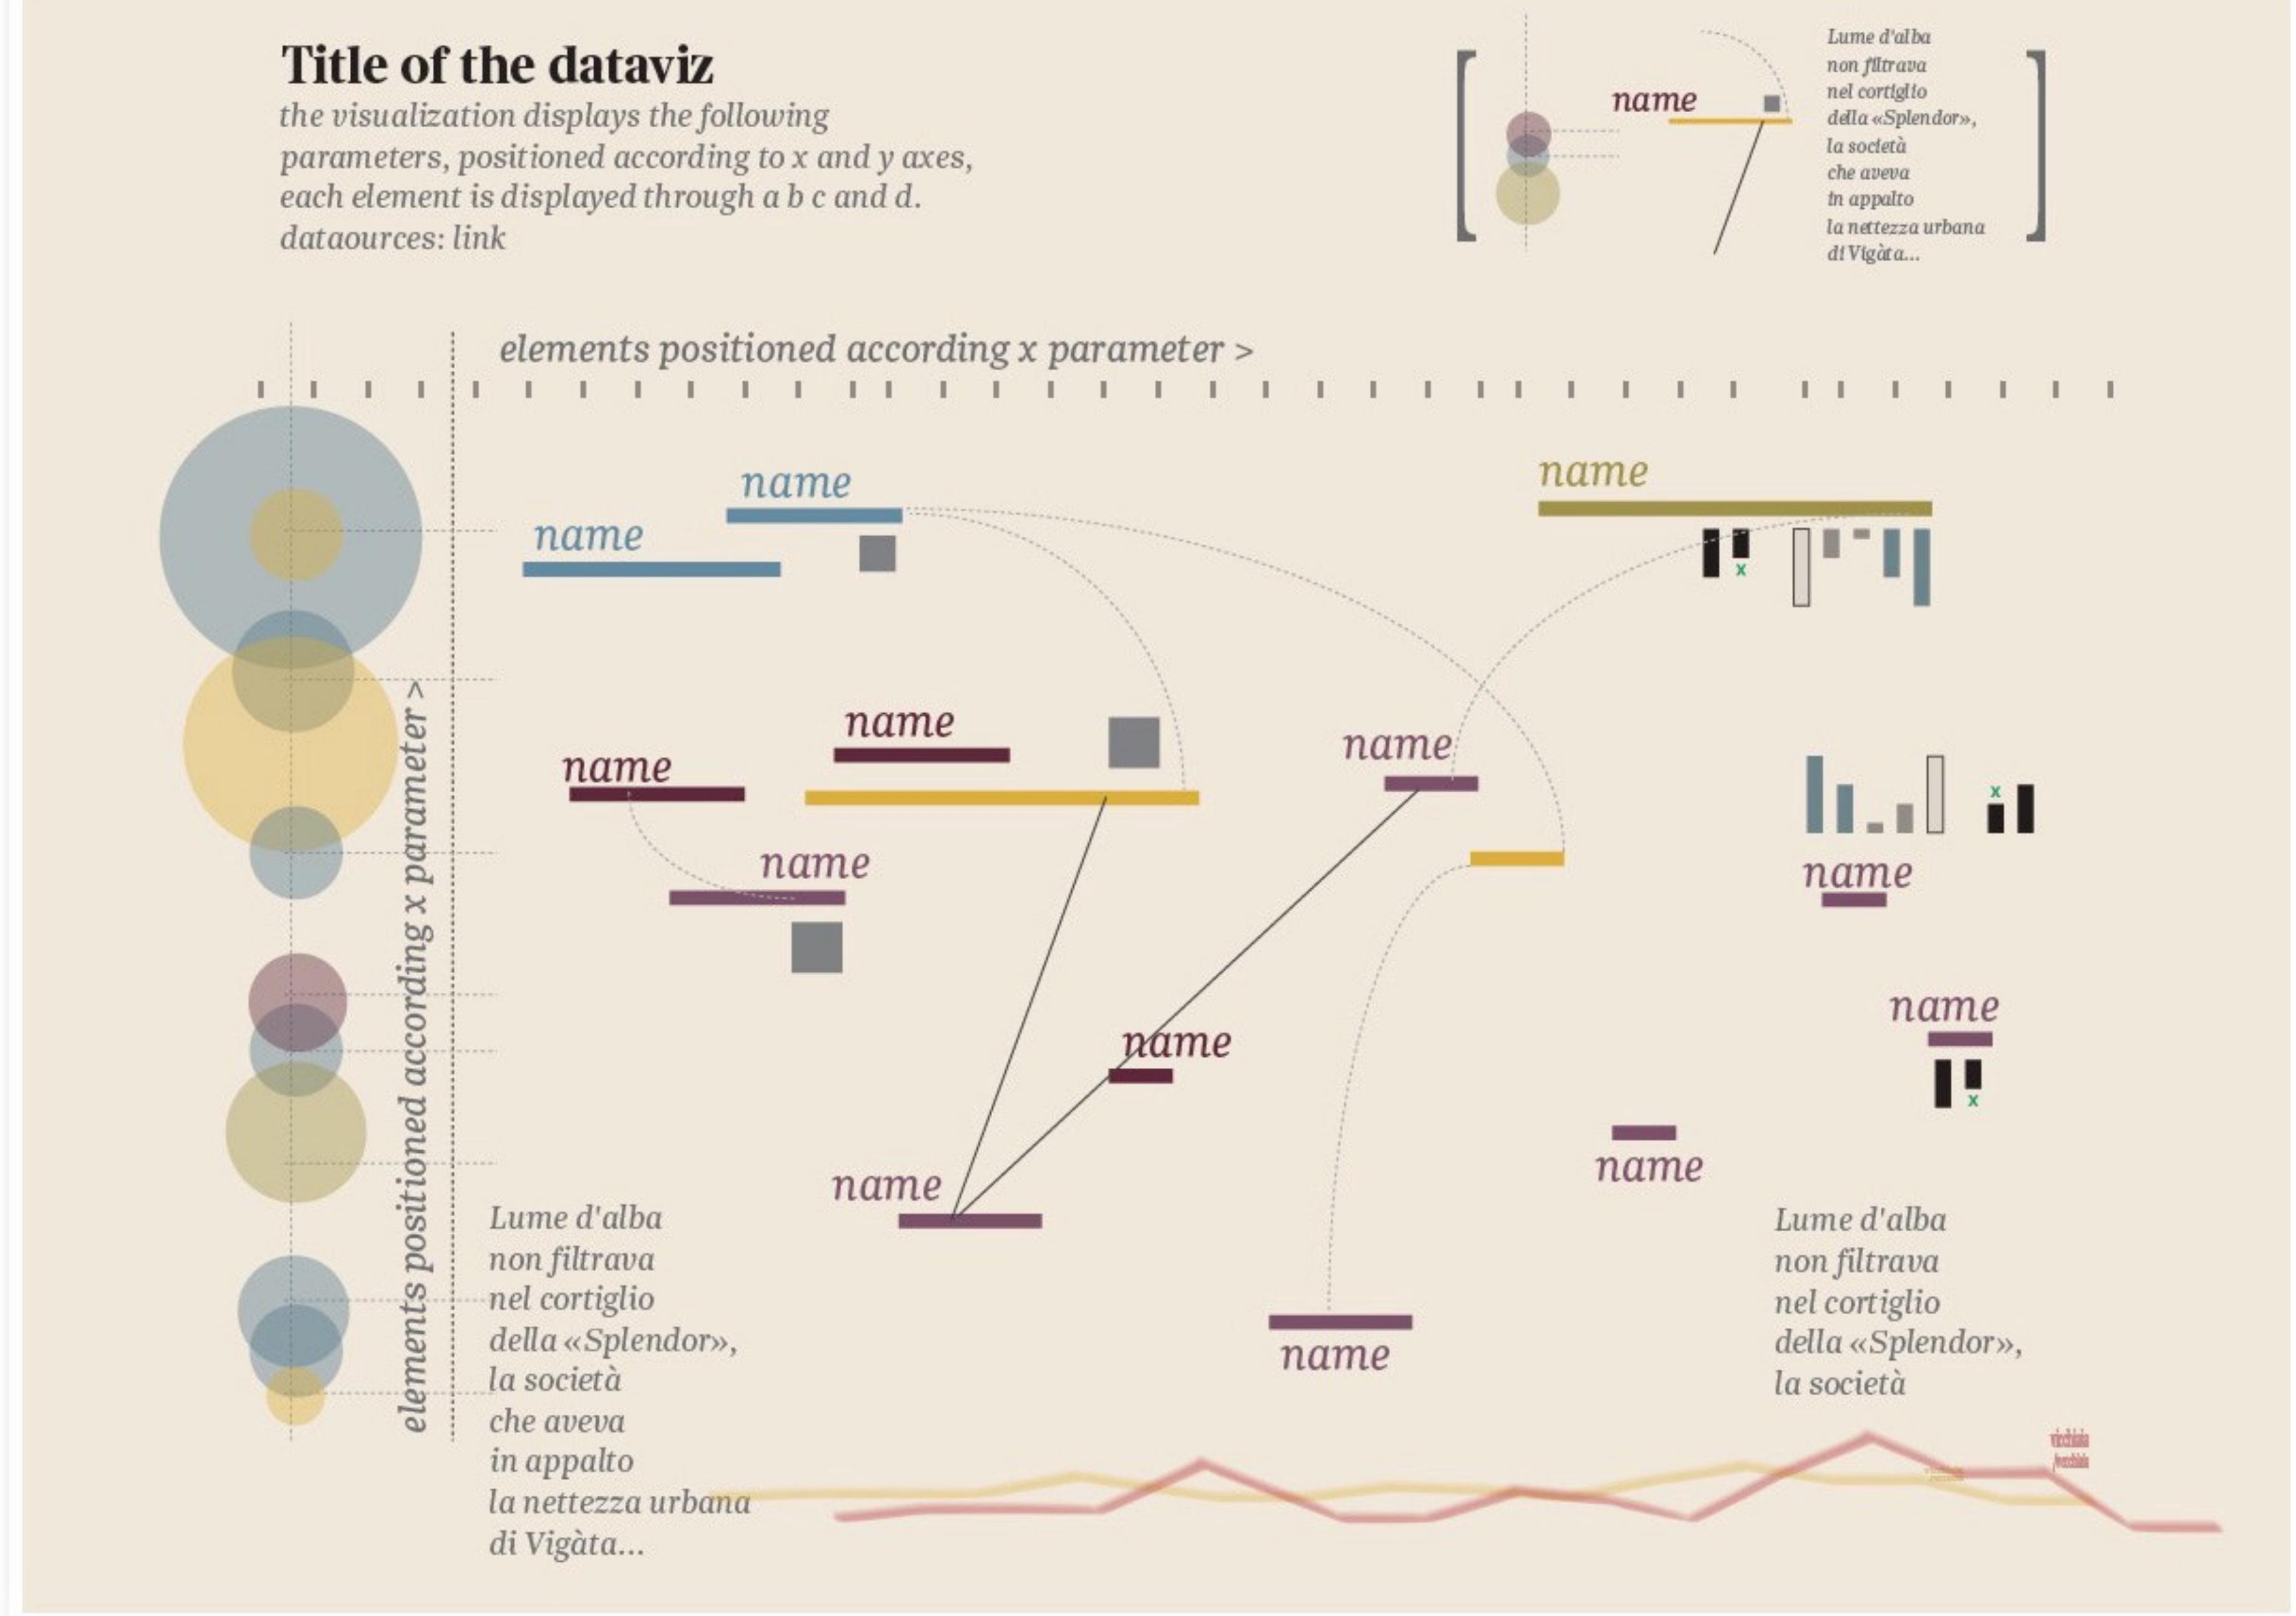

## DATA HUMANISM

small big data  
data bandwidth ~~quality~~  
  
imperfect infallible data  
subjective impartial data  
inspiring descriptive data  
serendipitous predictive data  
  
data conventions ~~possibilities~~  
data to simplify complexity / depict  
data processing ~~drawing~~  
data driven design  
  
Spend save time with  
  
data is numbers ~~people~~  
data will make us more efficient ~~human~~.

Her process involves layering multiple sub-narratives over a main construct. To achieve this multilayered storytelling with data ... everything depends on the concept of layering, establishing hierarchies, and making them clear.

## Title of the dataviz

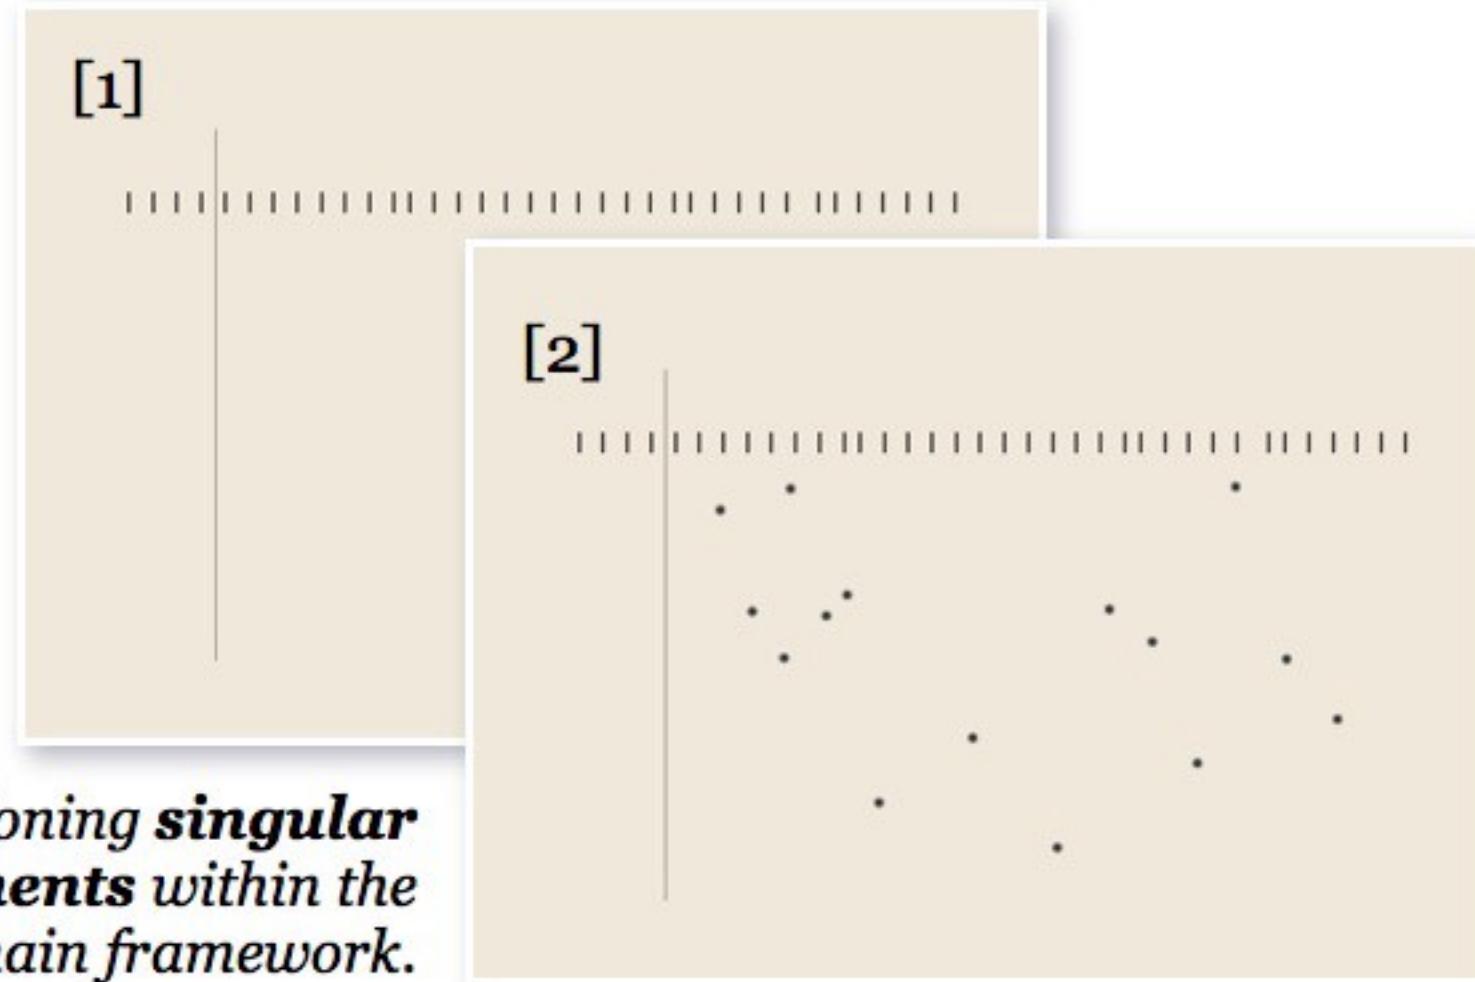

the visualization displays the following parameters, positioned according to x and y axes, each element is displayed through a b c and d. datasources: link

# Layering, and making hierarchies clear

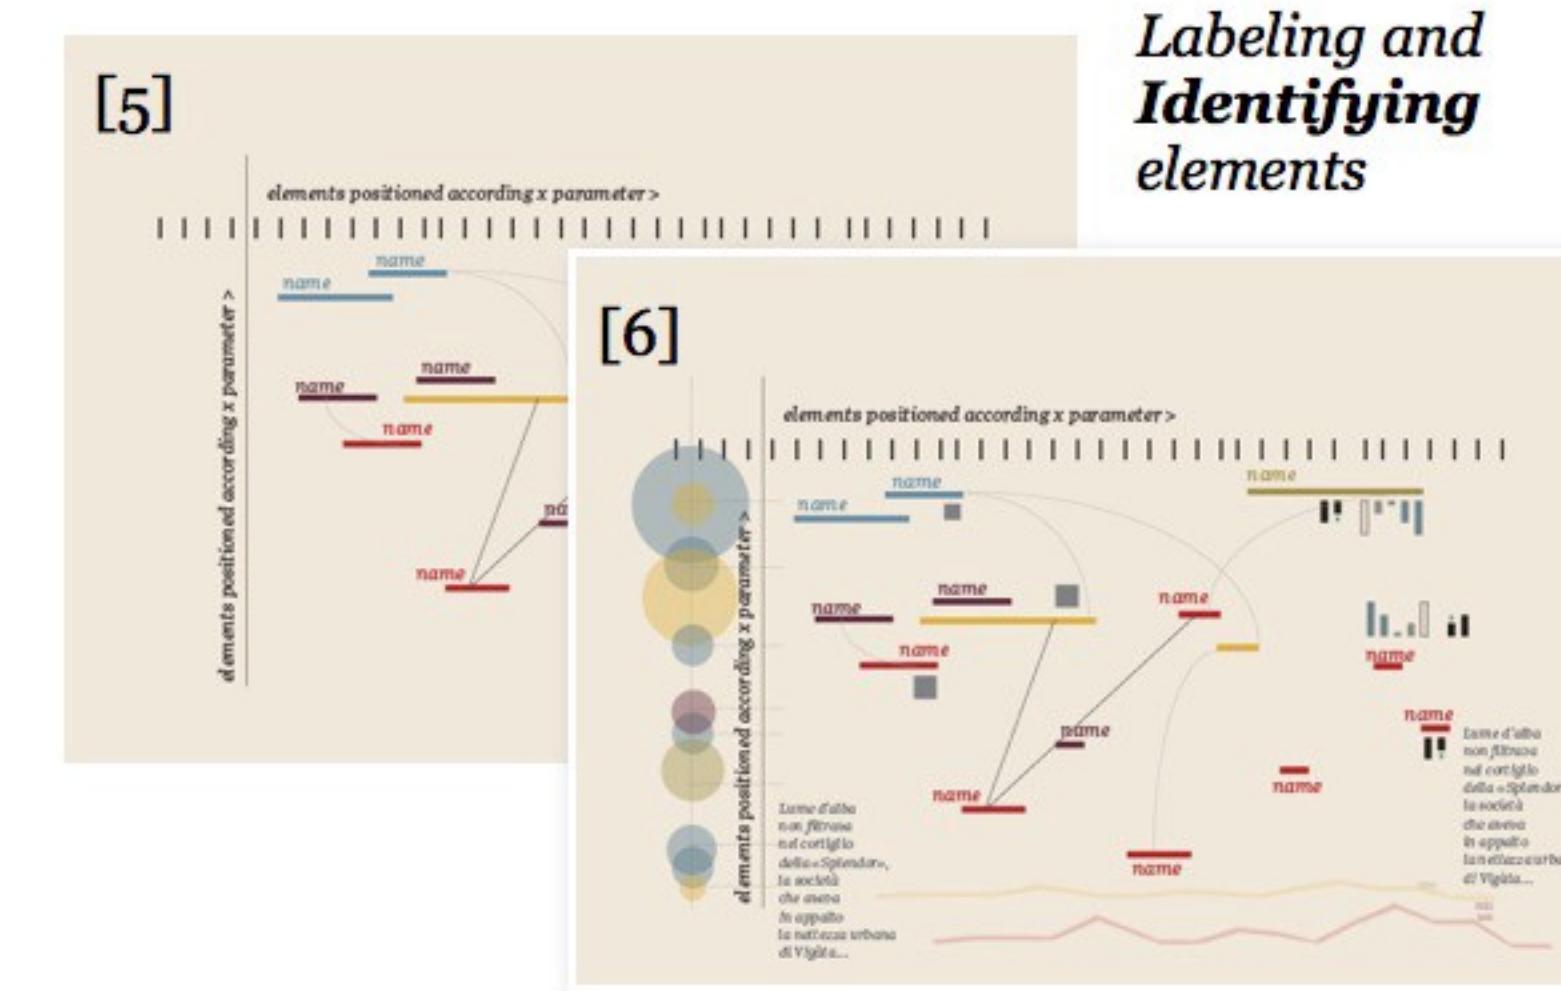

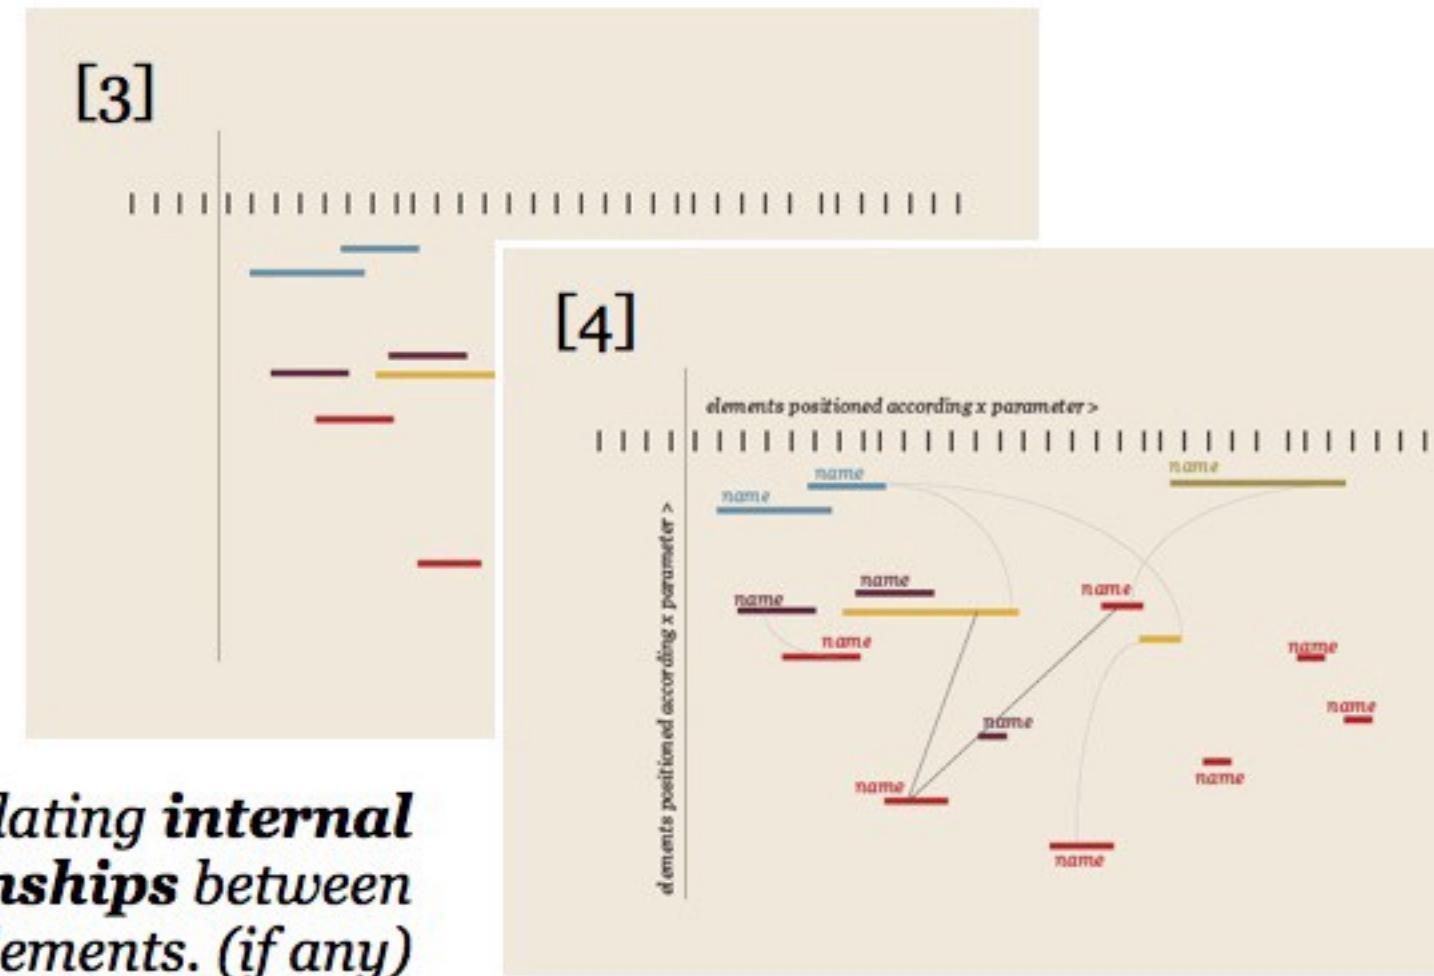

*Composing the main architecture of the visualization*

*Positioning singular elements within the main framework.*

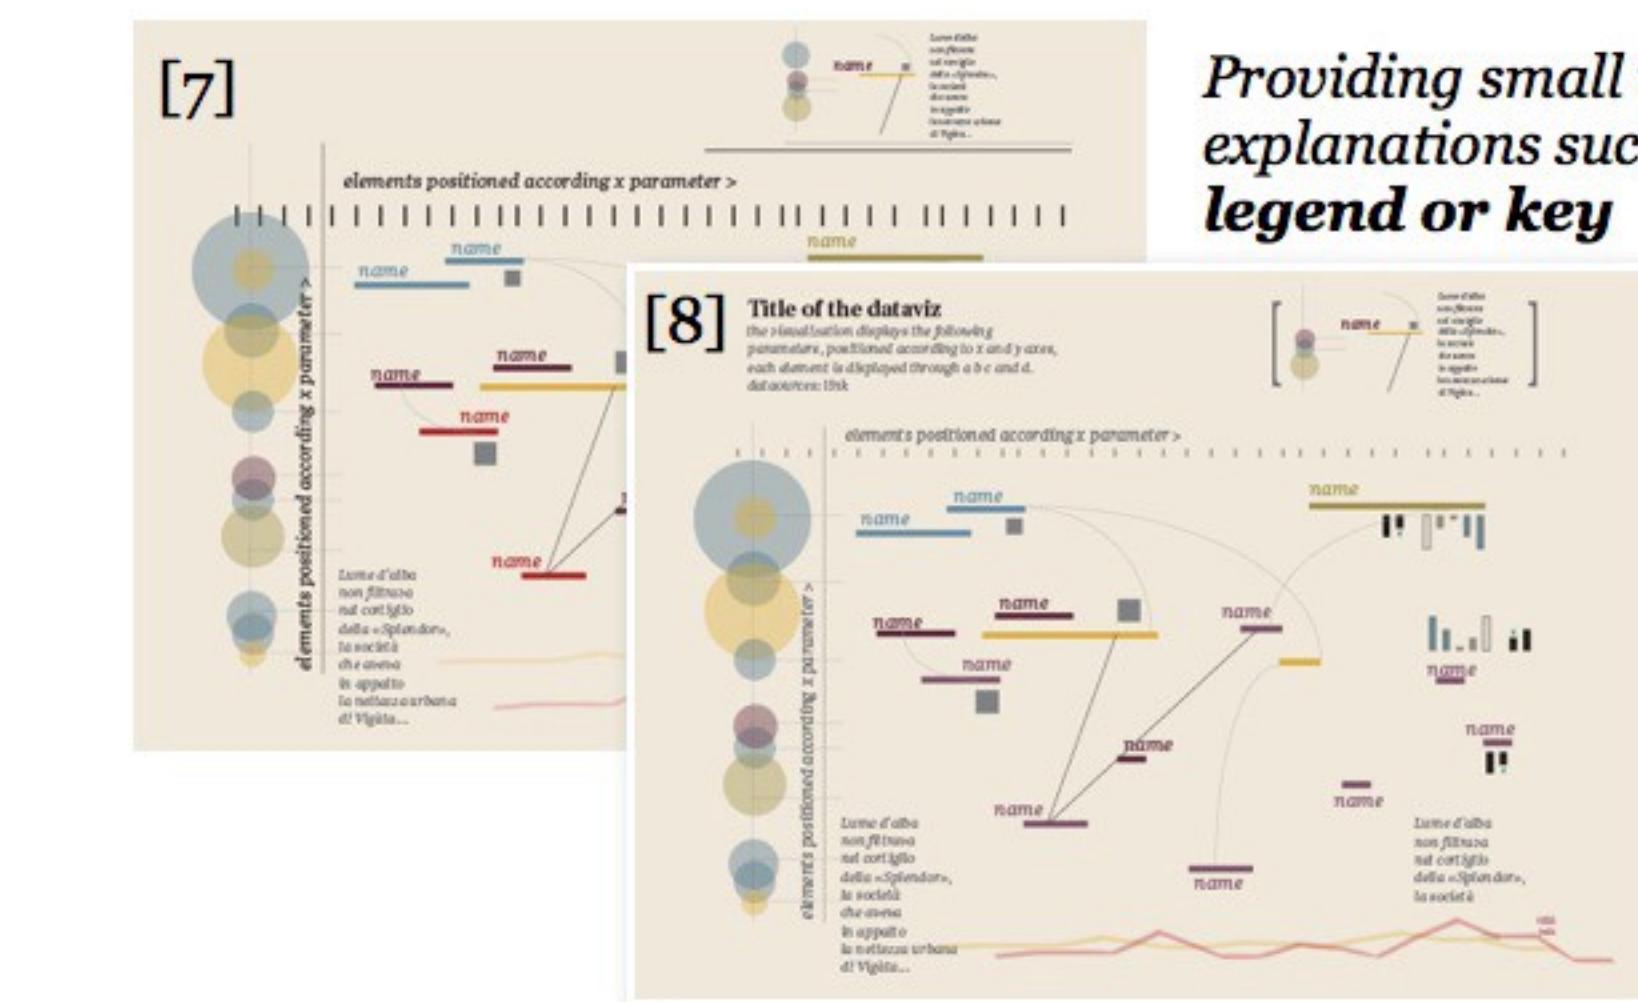

*Constructing shaped elements of dimensionality and form*

*Elucidating internal relationships between elements. (if any)*

*Labeling and Identifying elements*

*Supplementing the greater story through the addition of “minor or tangential tales” elements*

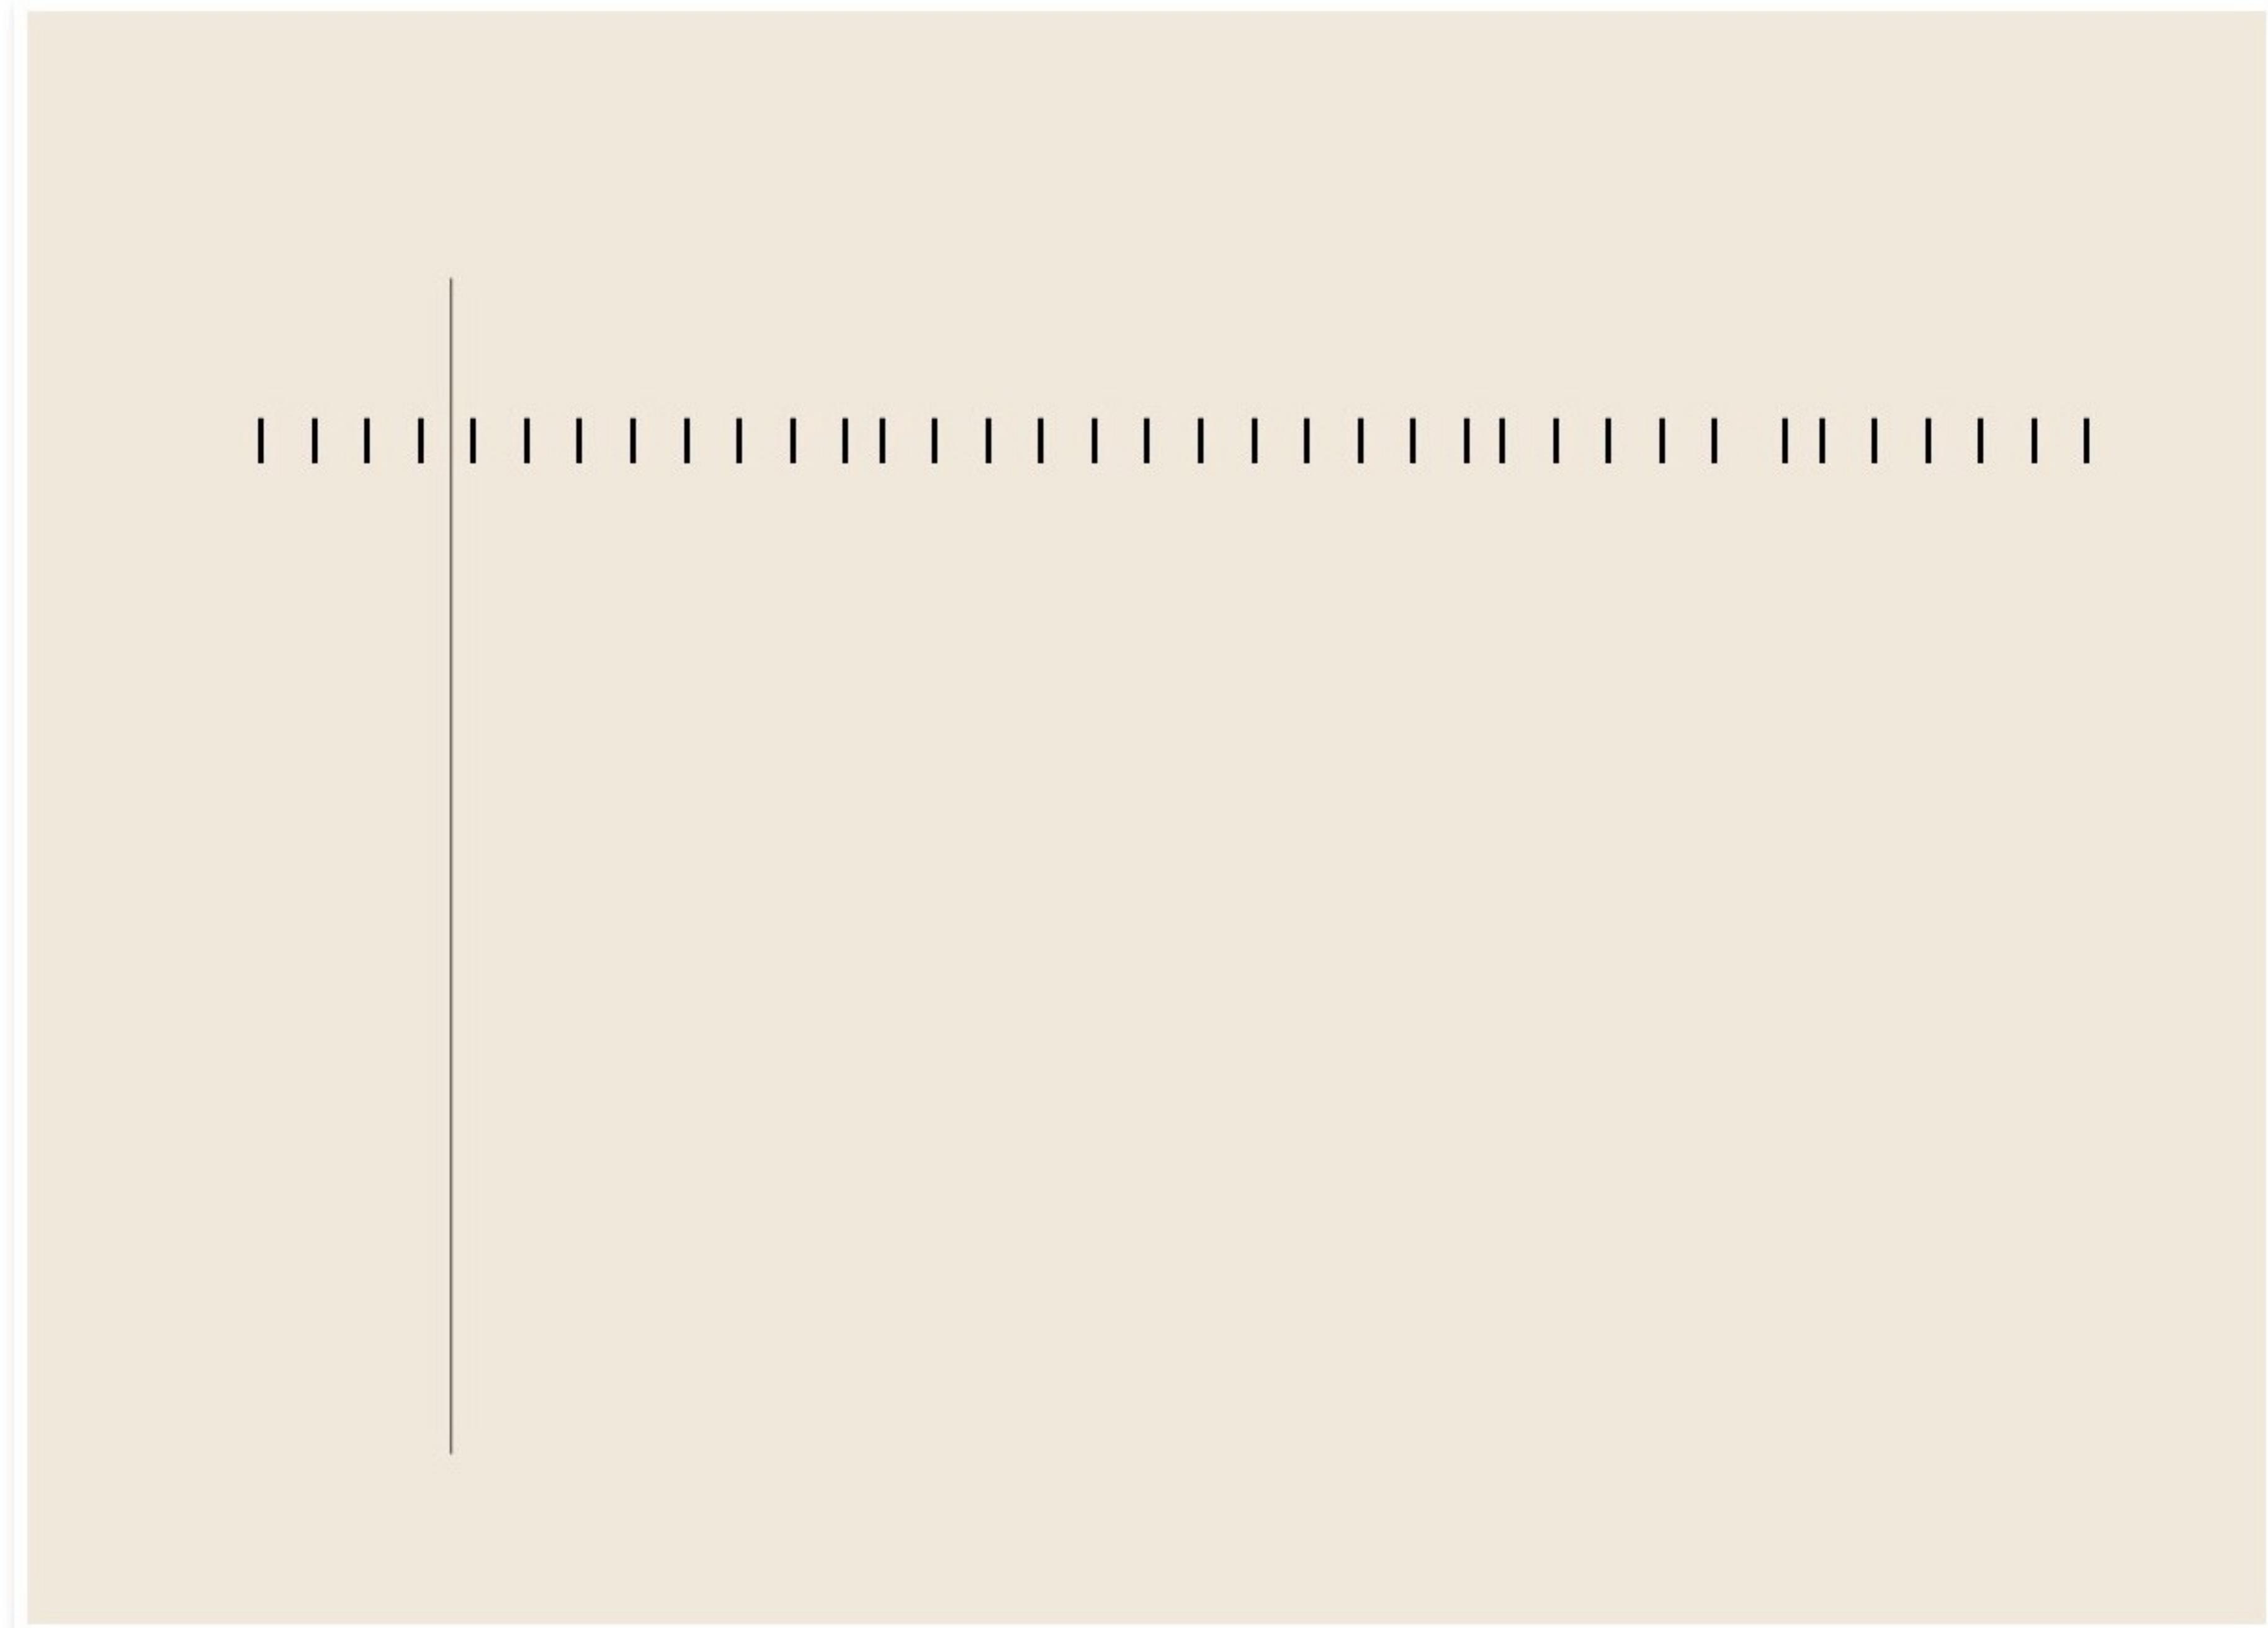

*Providing small visual explanations such as a legend or key*

*Fine-tuning and stylizing of elements shapes, colors, and weights to make hierarchies pop out.*

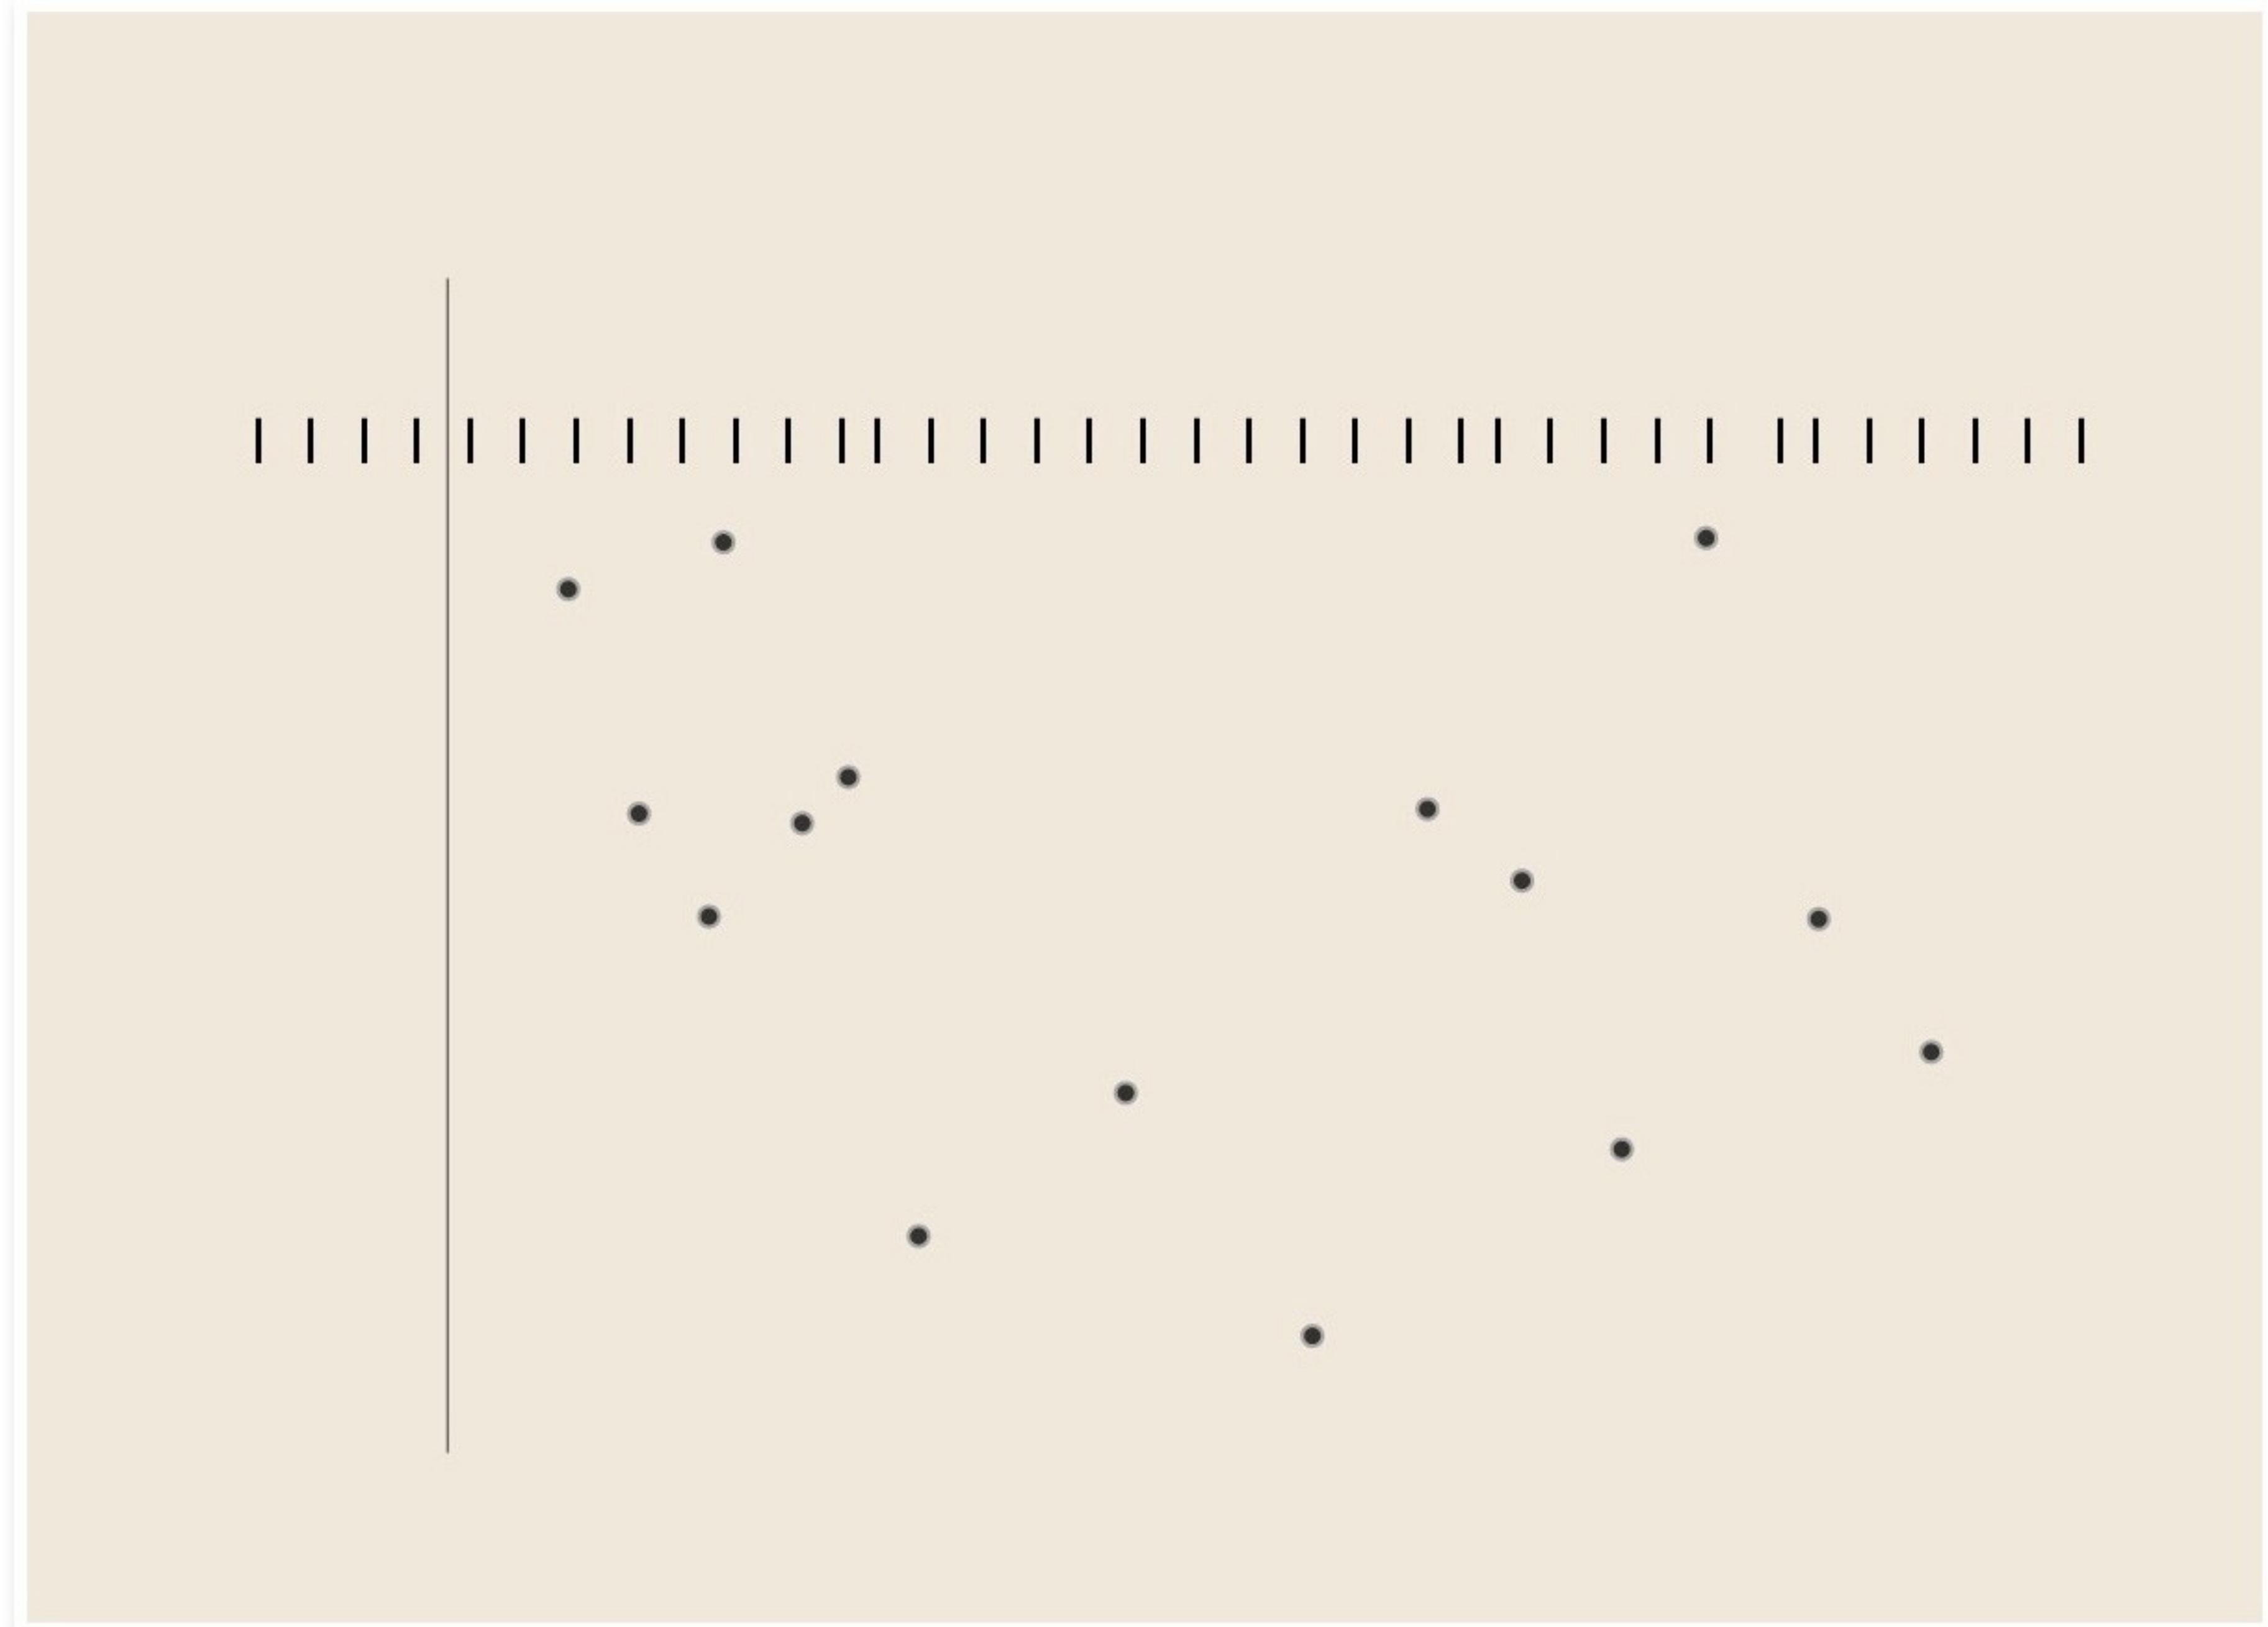

## [1] Composing the main architecture of the visualization

Composing the main architecture: this acts as the formalized base through which the main story will be mapped and displayed, upon this, one will see the most relevant patterns emerging from the story: the essential “map” that conceptually identifies where we are. This base is essentially a matrix or pattern that will serve as our organizer. It may be composed of cells, or distances, or other interrelated multiples.

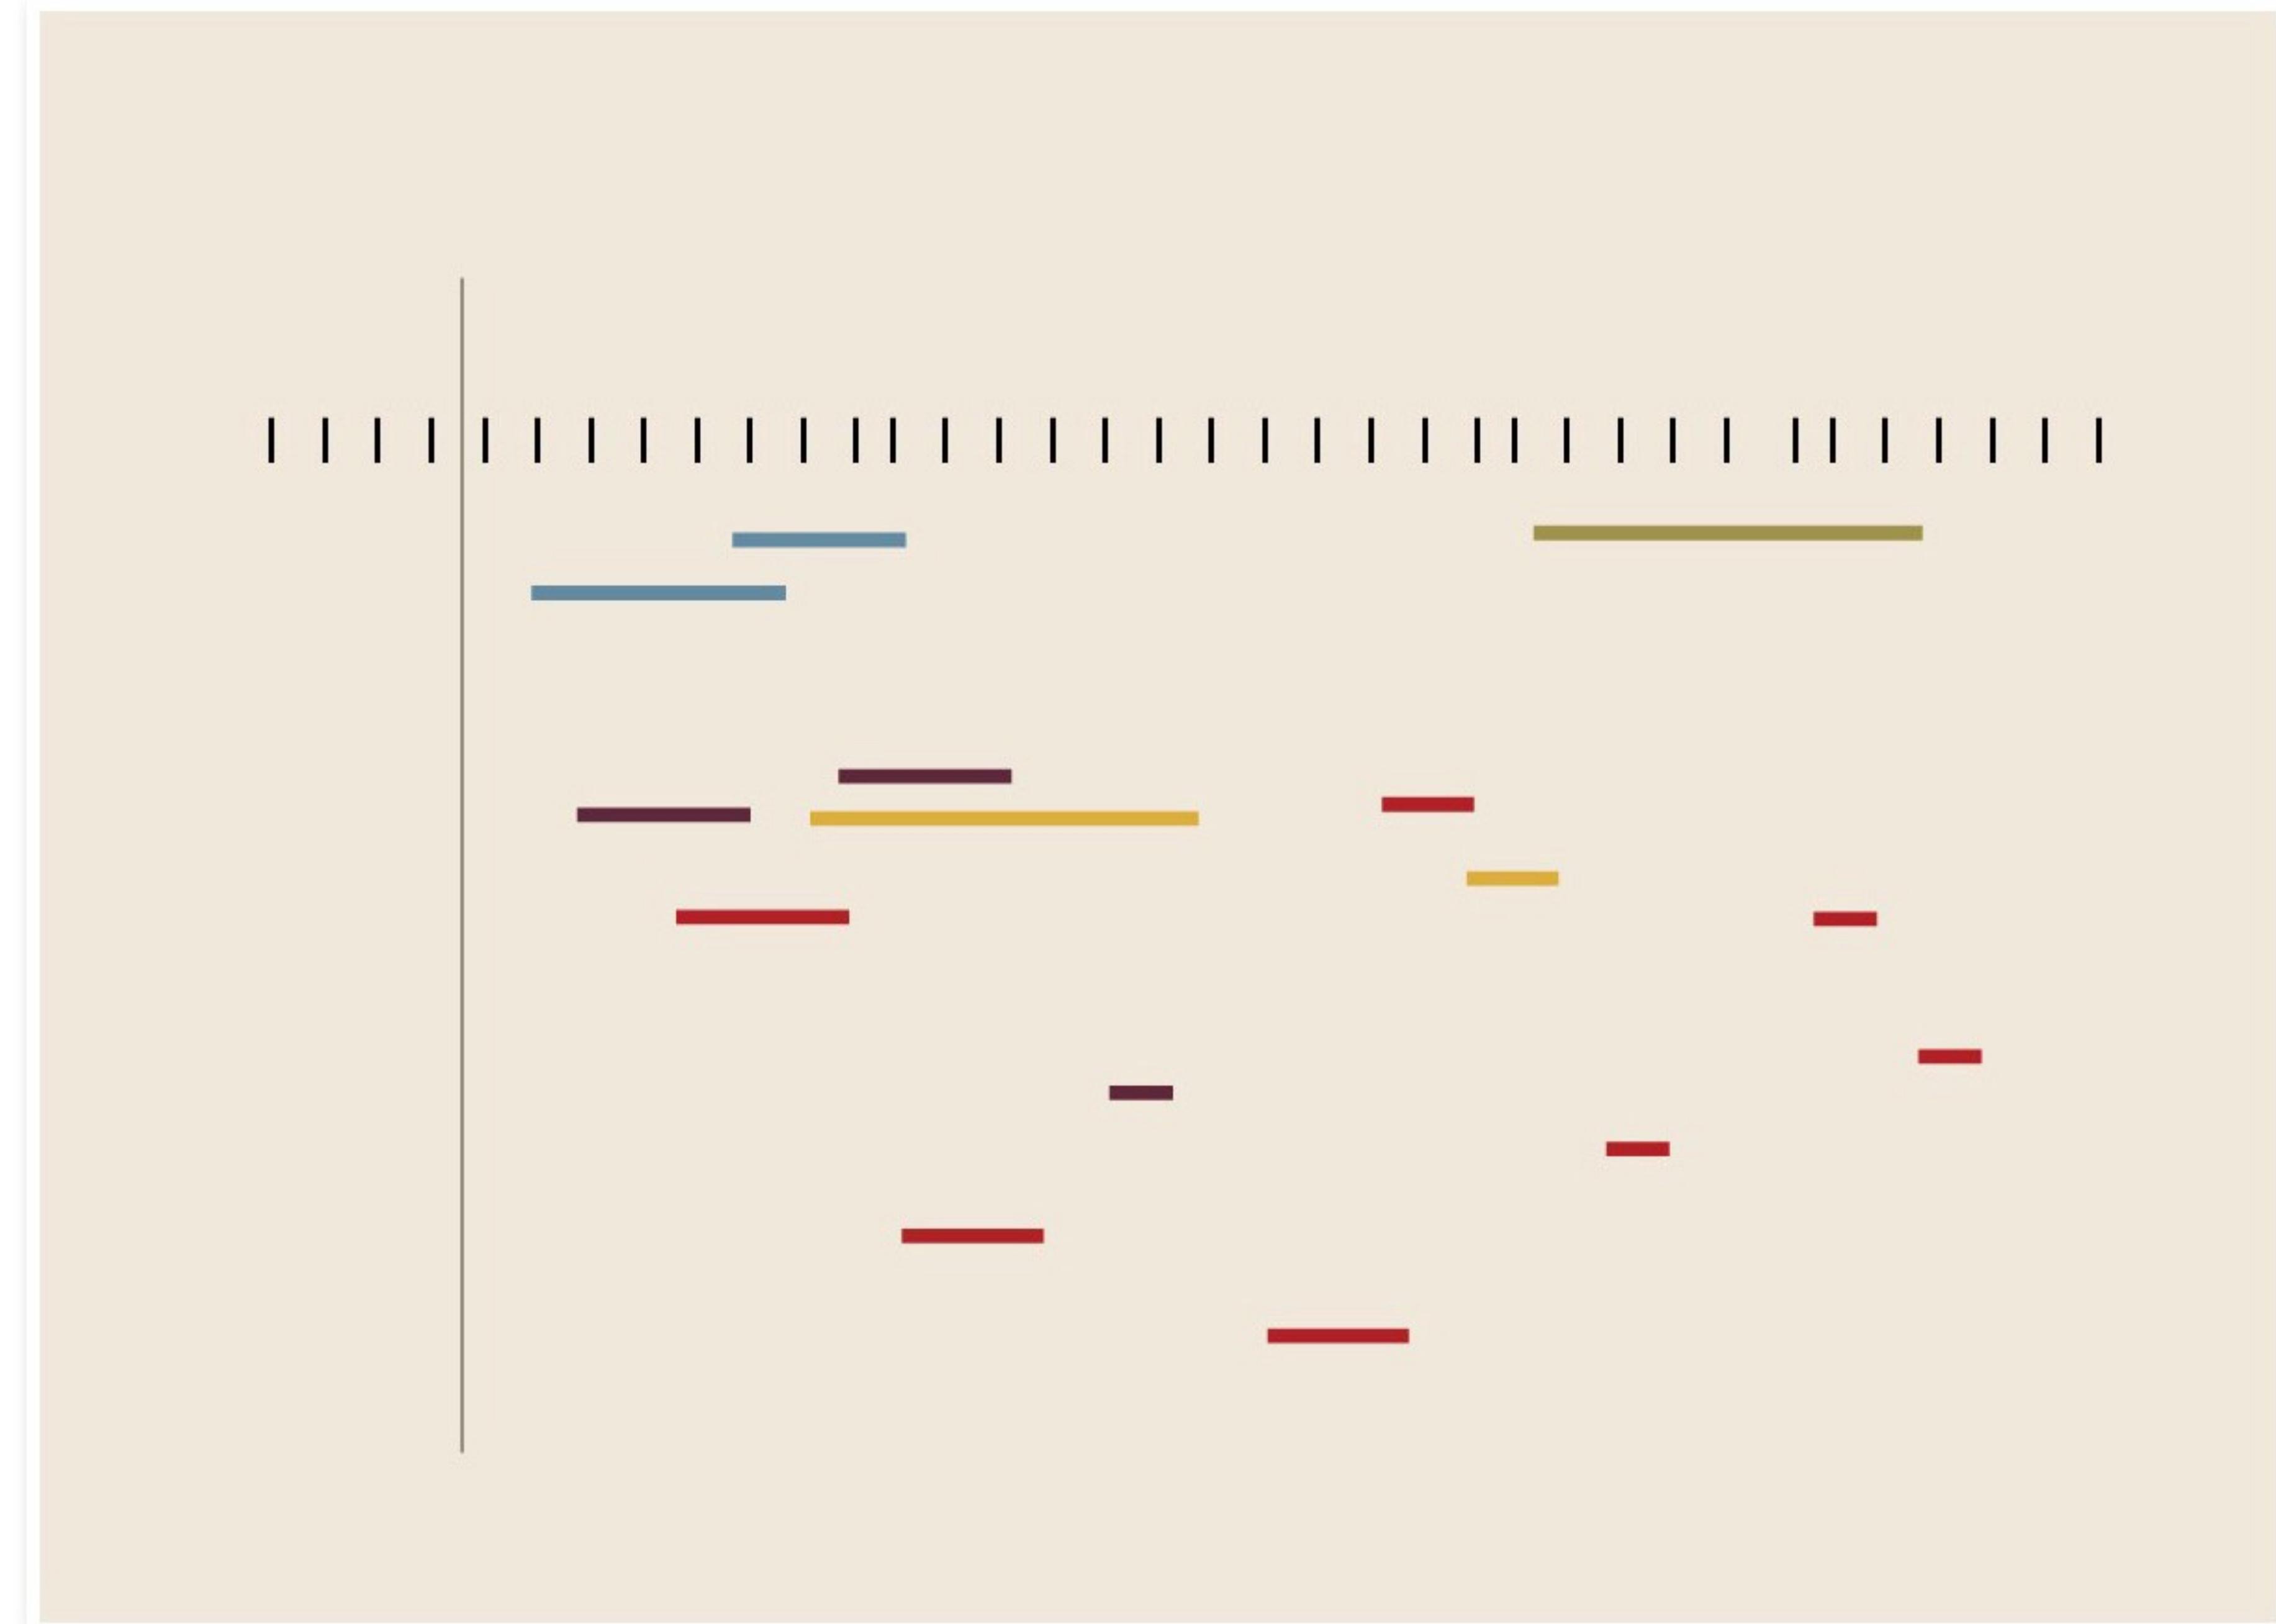

## [2] Positioning singular elements within the main framework.

This process will test the effectiveness of the main architecture; the placement of elements reveals or confirms weaknesses and strengths, which may lead to modification of the main architecture.

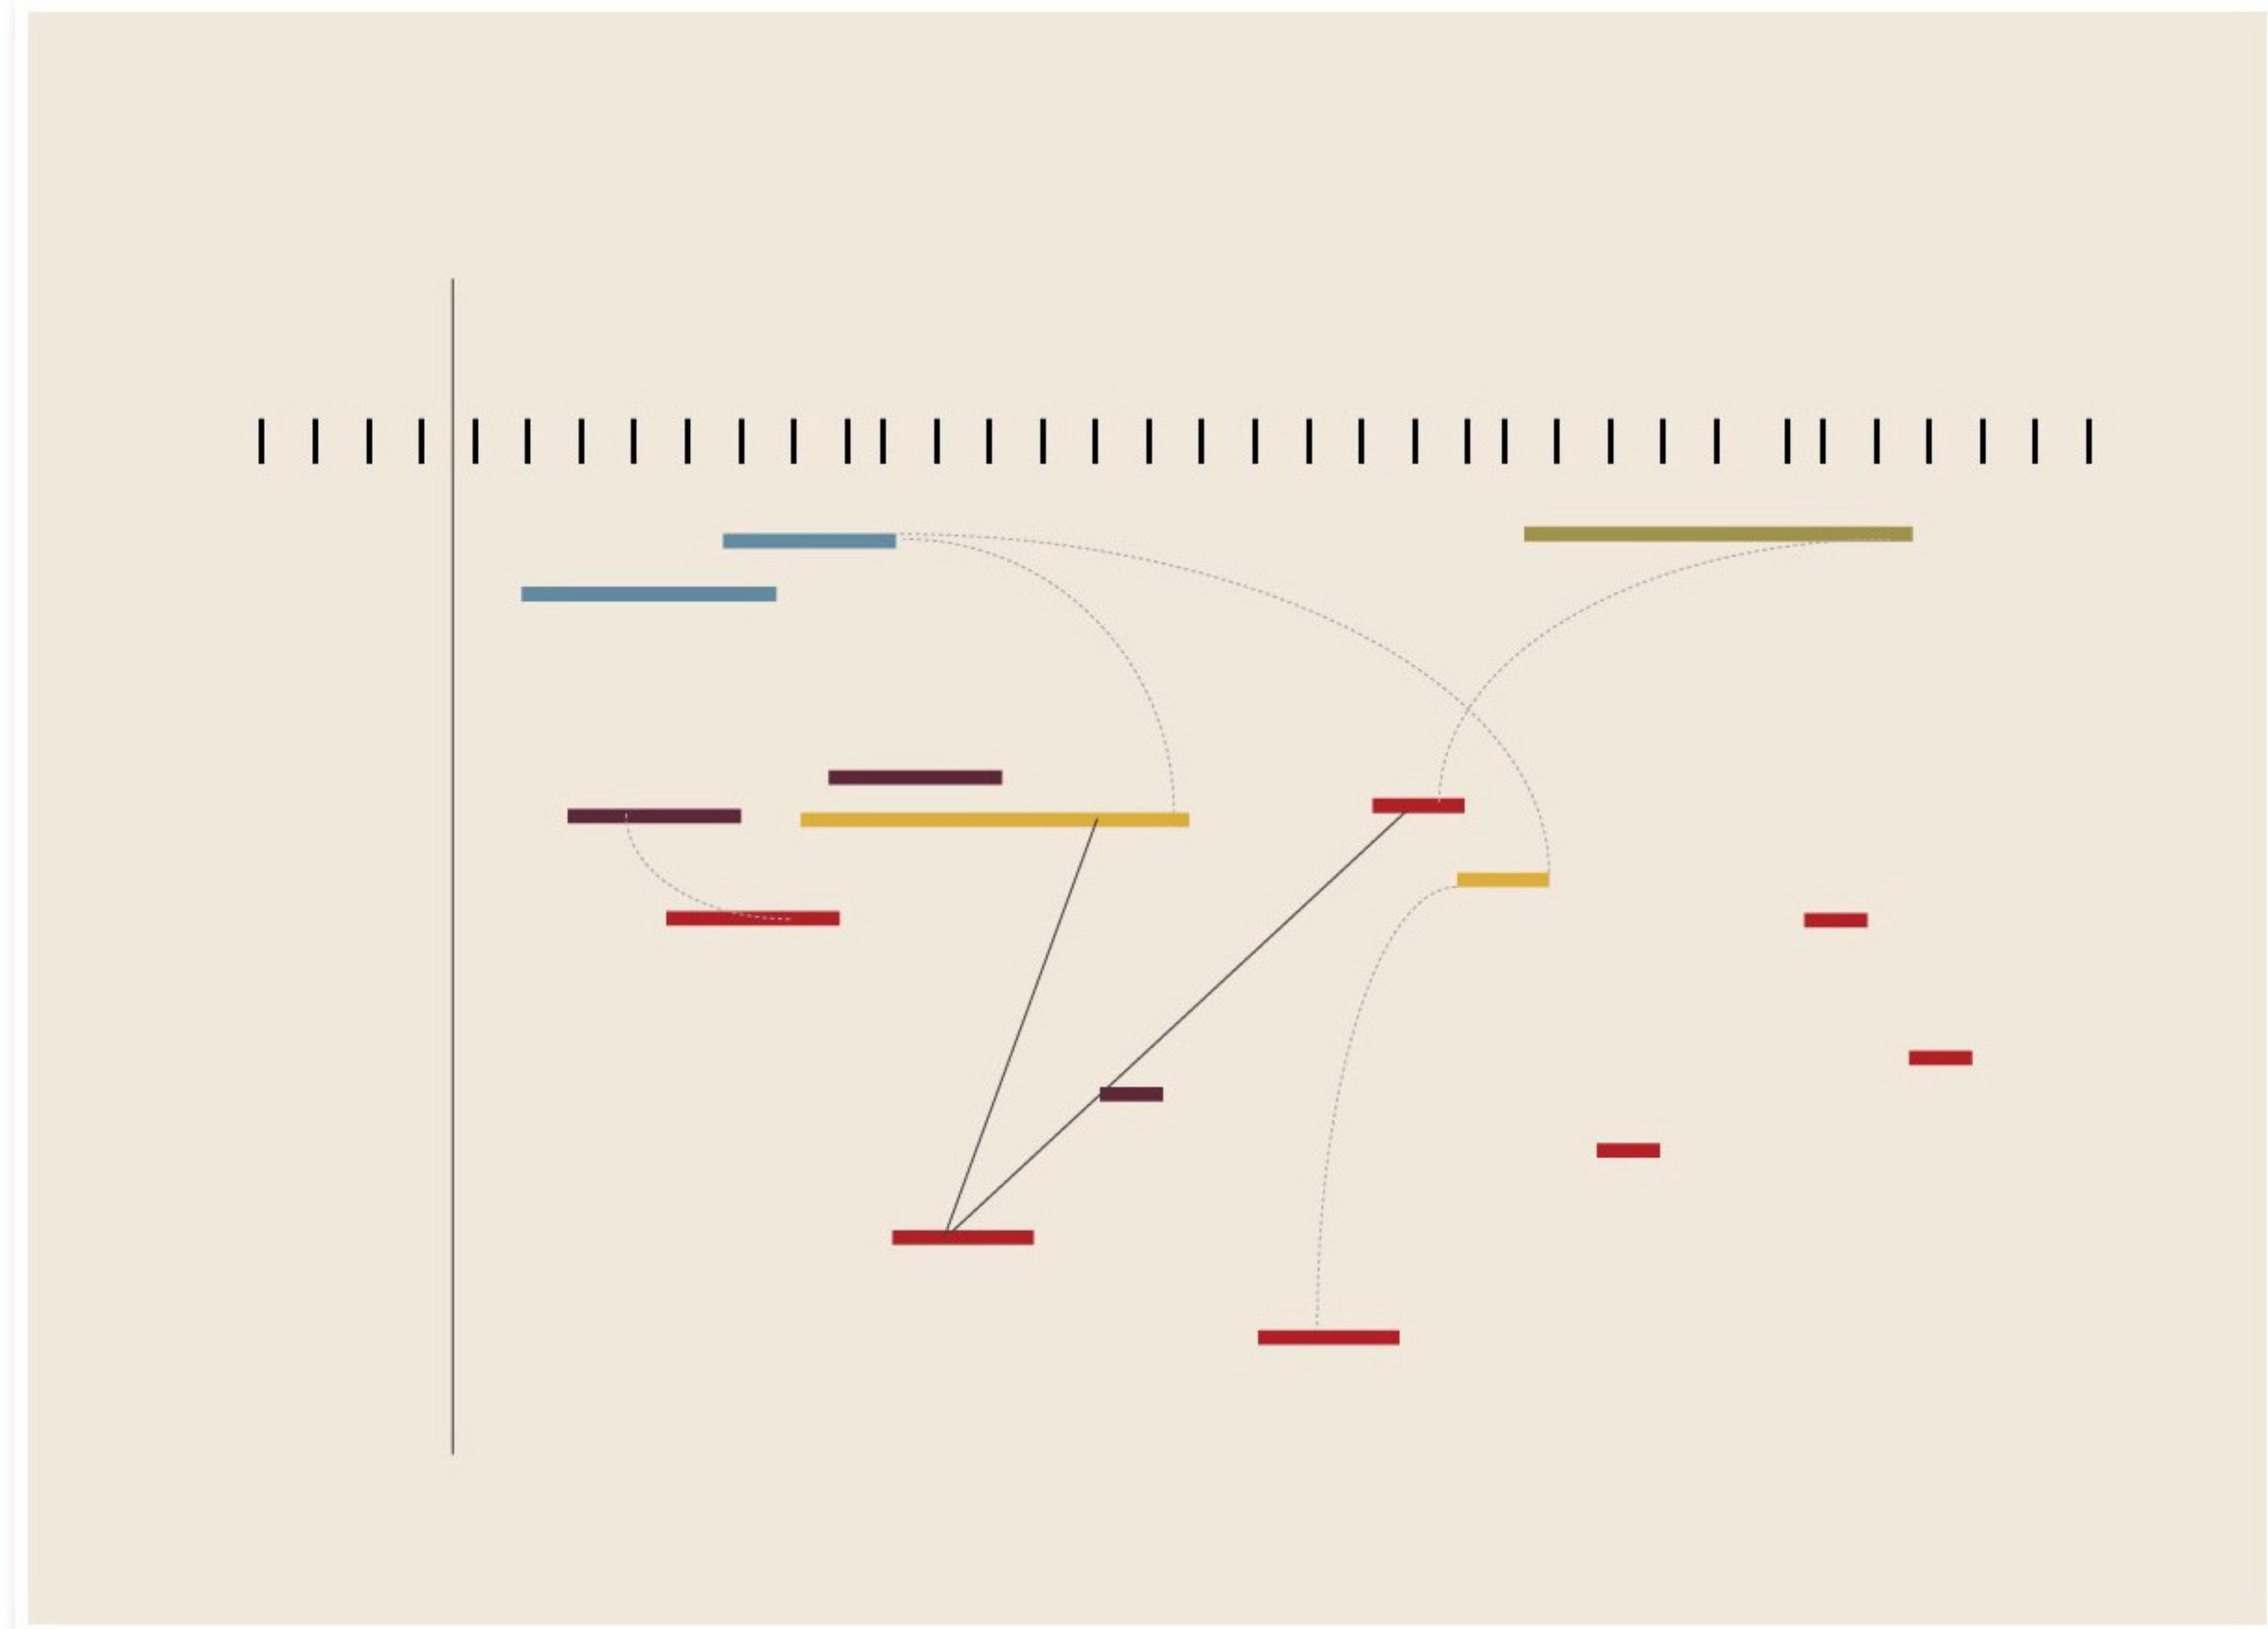

### [3] Constructing shaped elements of dimensionality and form

Constructing shaped elements of dimensionality and form (essentially polygons) with quantitative and qualitative parameters and positioning these within the main architecture. As these elements have form they must also be identified through colors according to opportunities to establish categorizations, thus advancing clarity and relationships that serve to enhance the story.

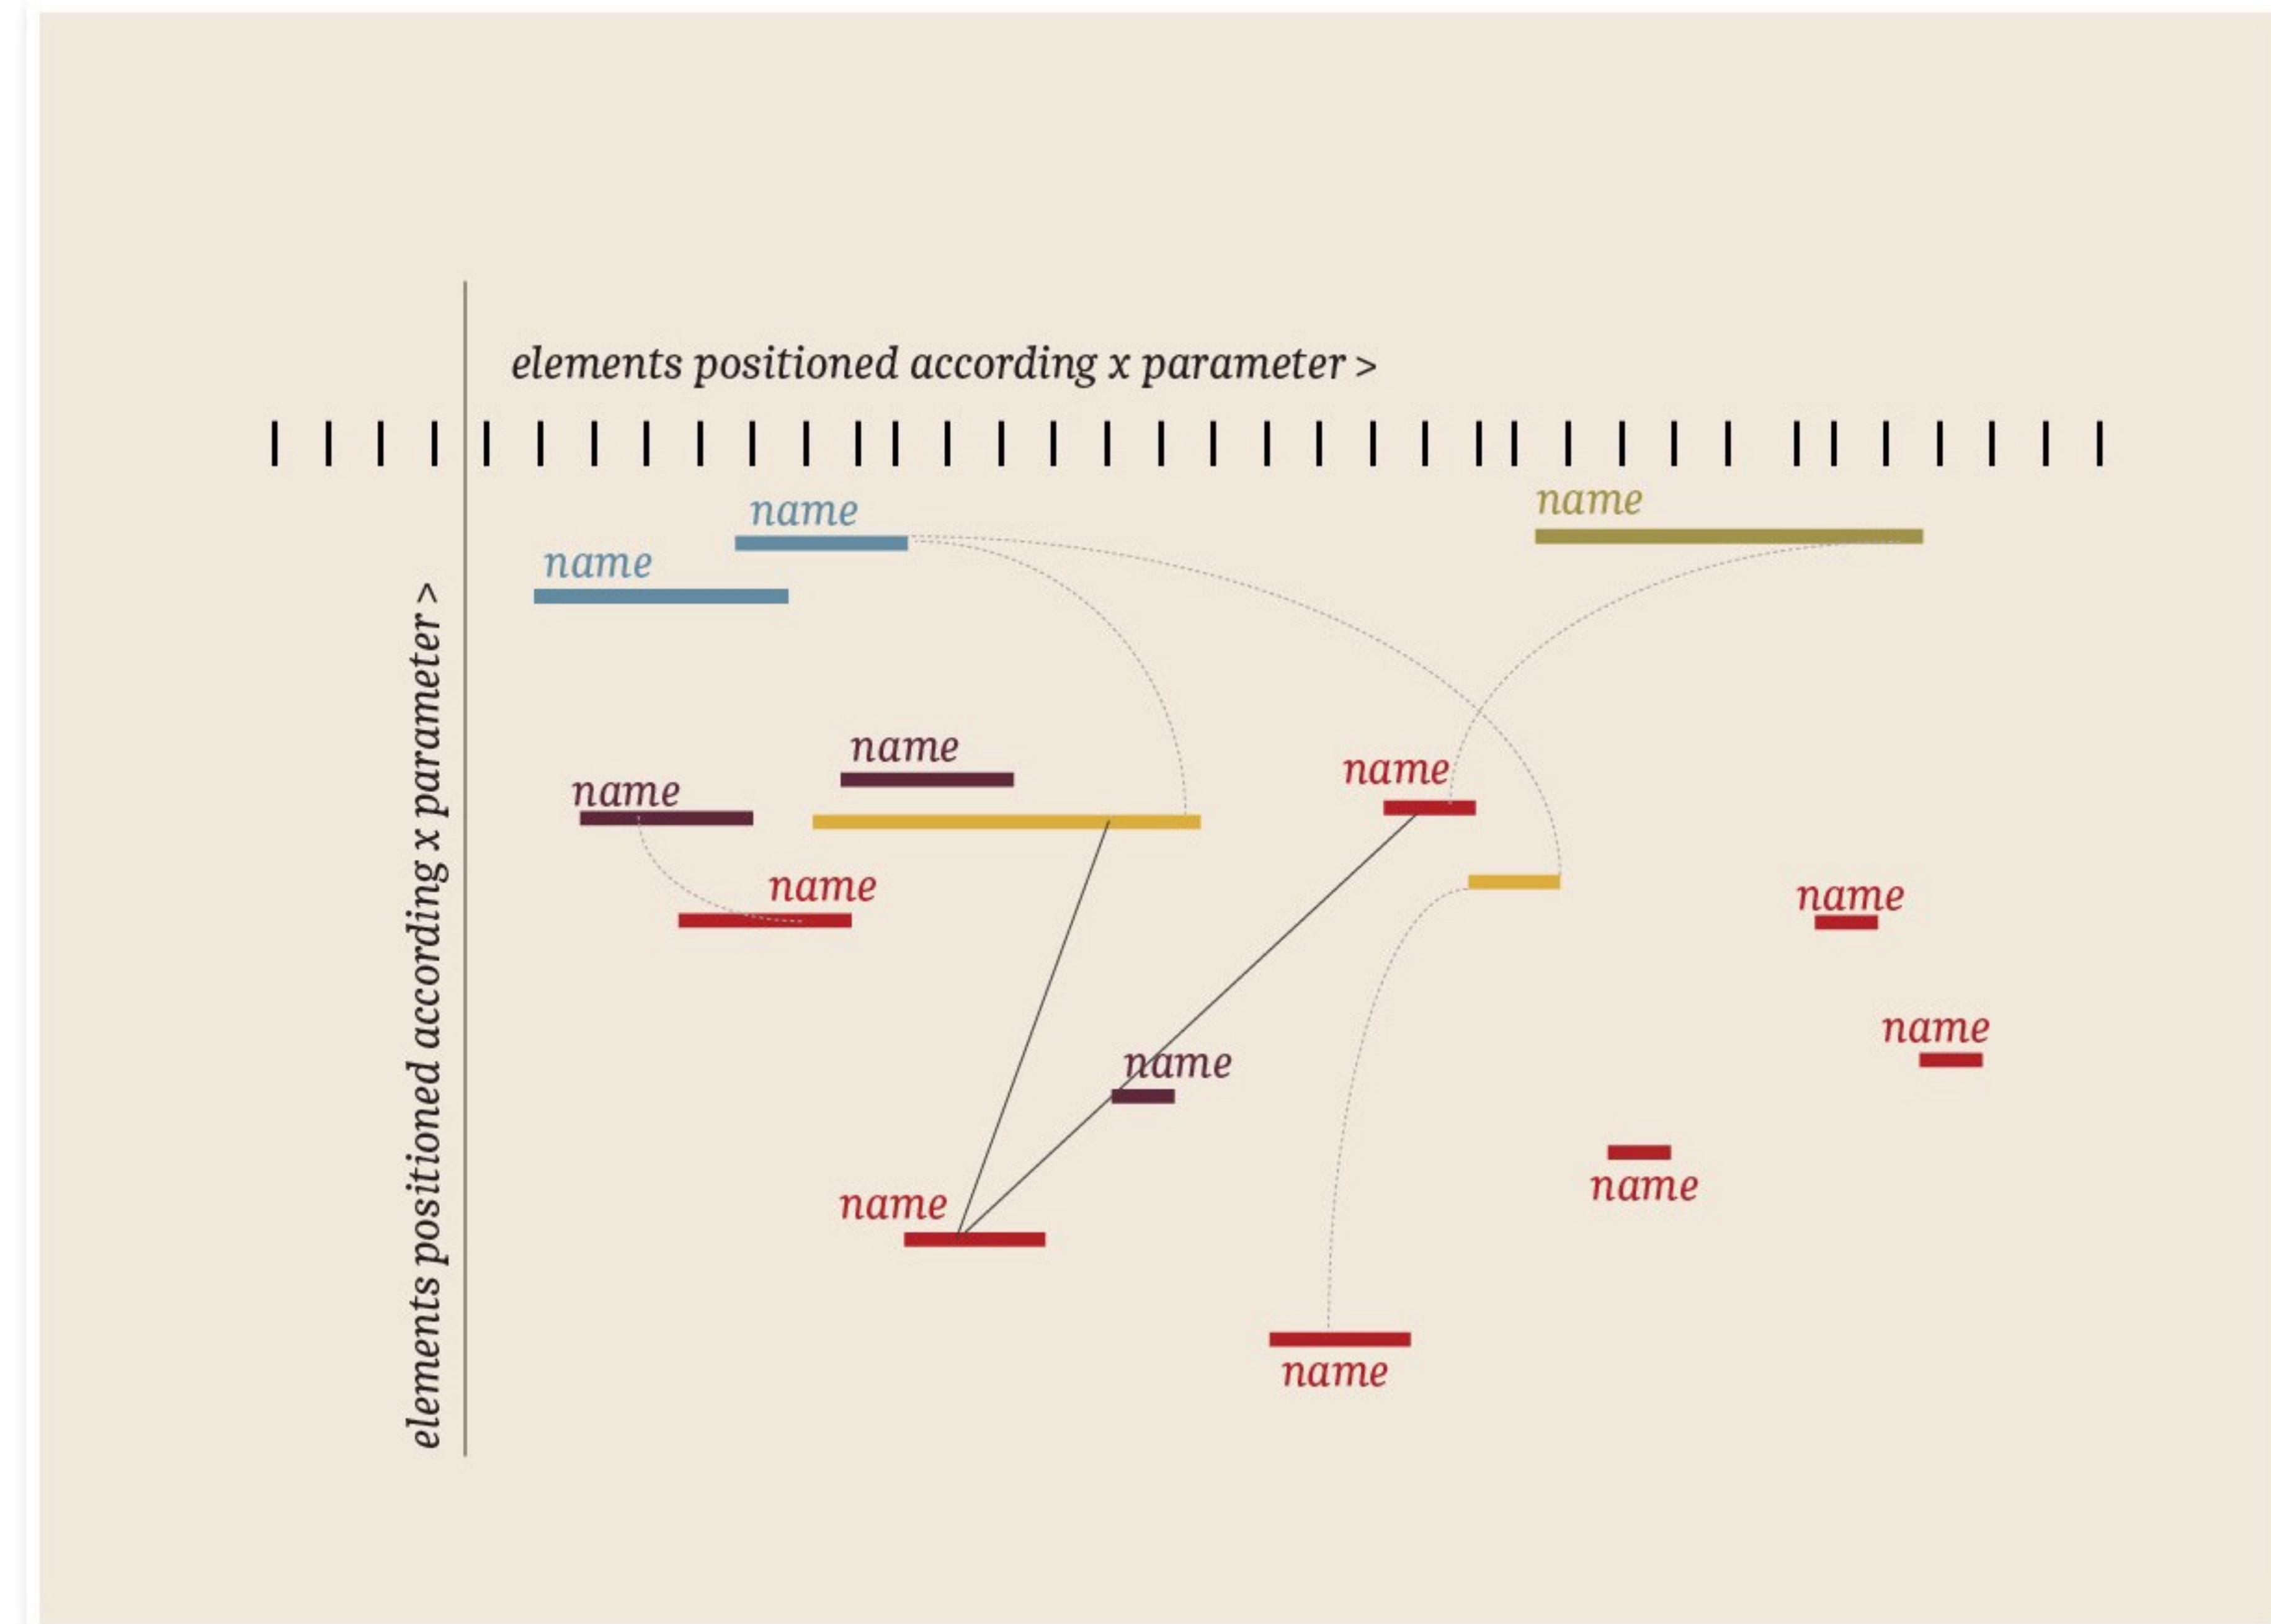

#### [4] Elucidating internal relationships between elements (if any)

These links, directives, and qualifiers serve to give the story a comprehensive texture and correlate dependencies within the story.

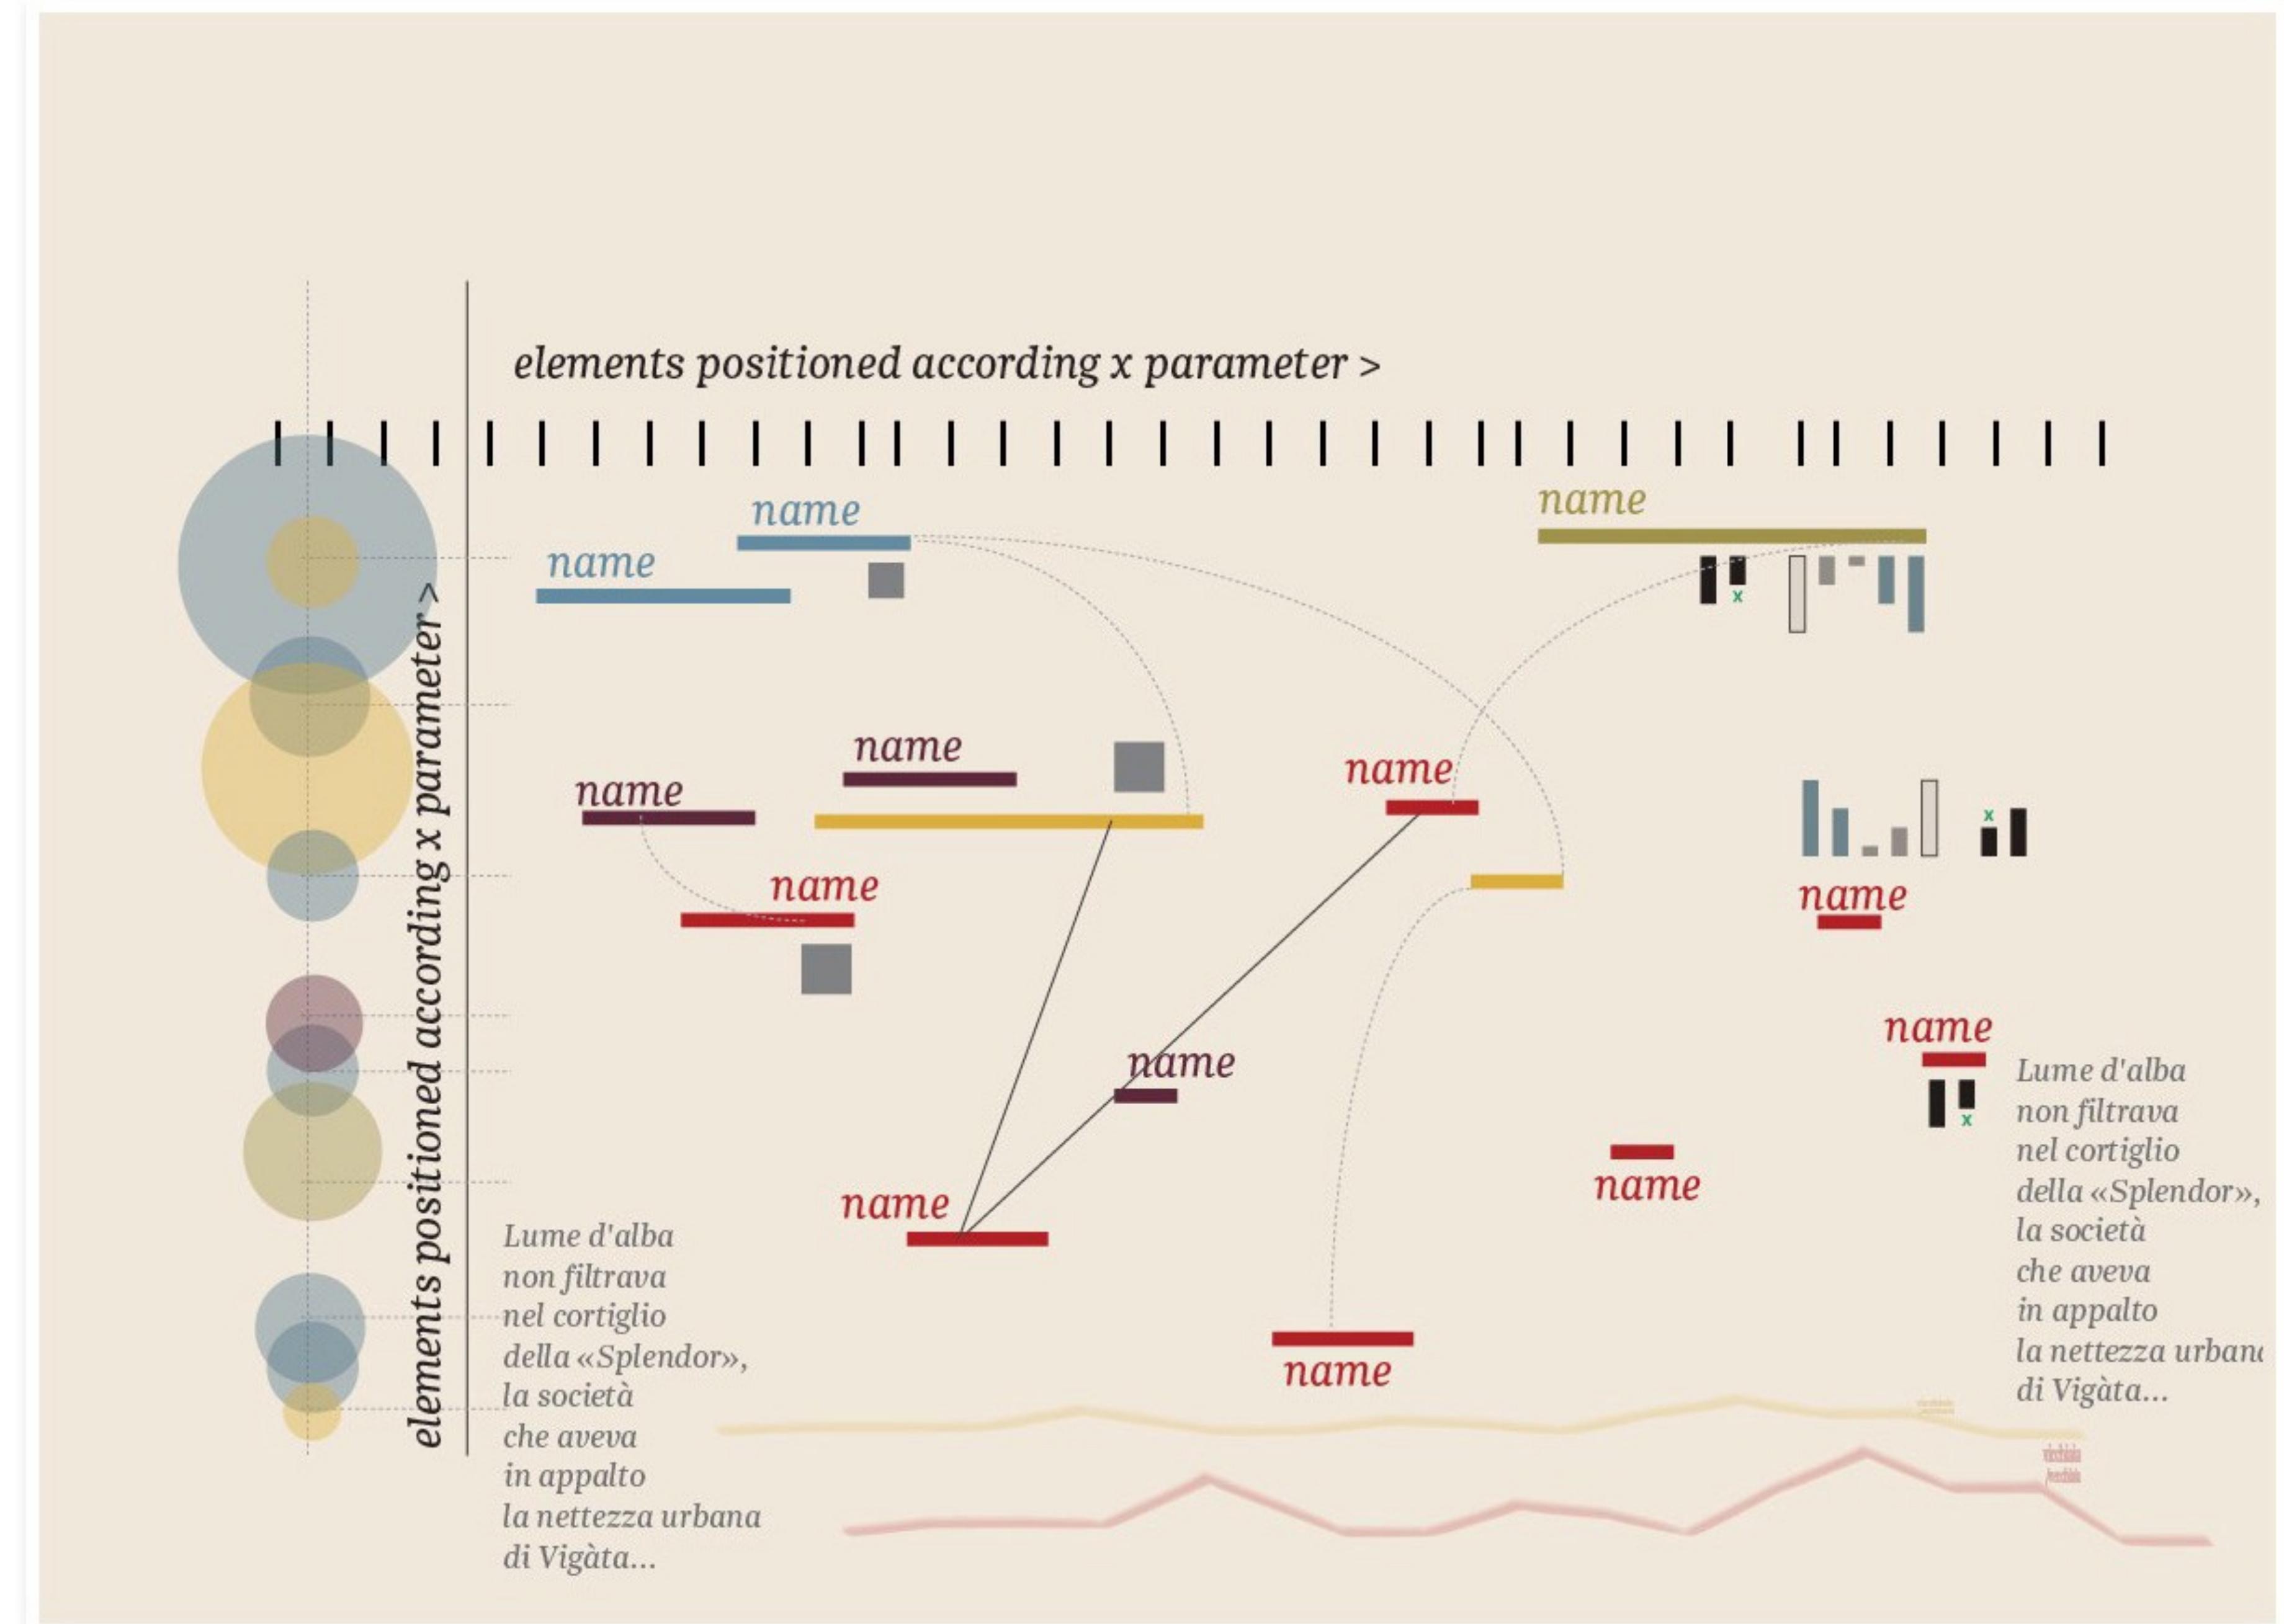

## [5] Labeling and identifying

Through the addition of explanatory labels and short texts we provide requisite last mile clarity throughout the presentation.

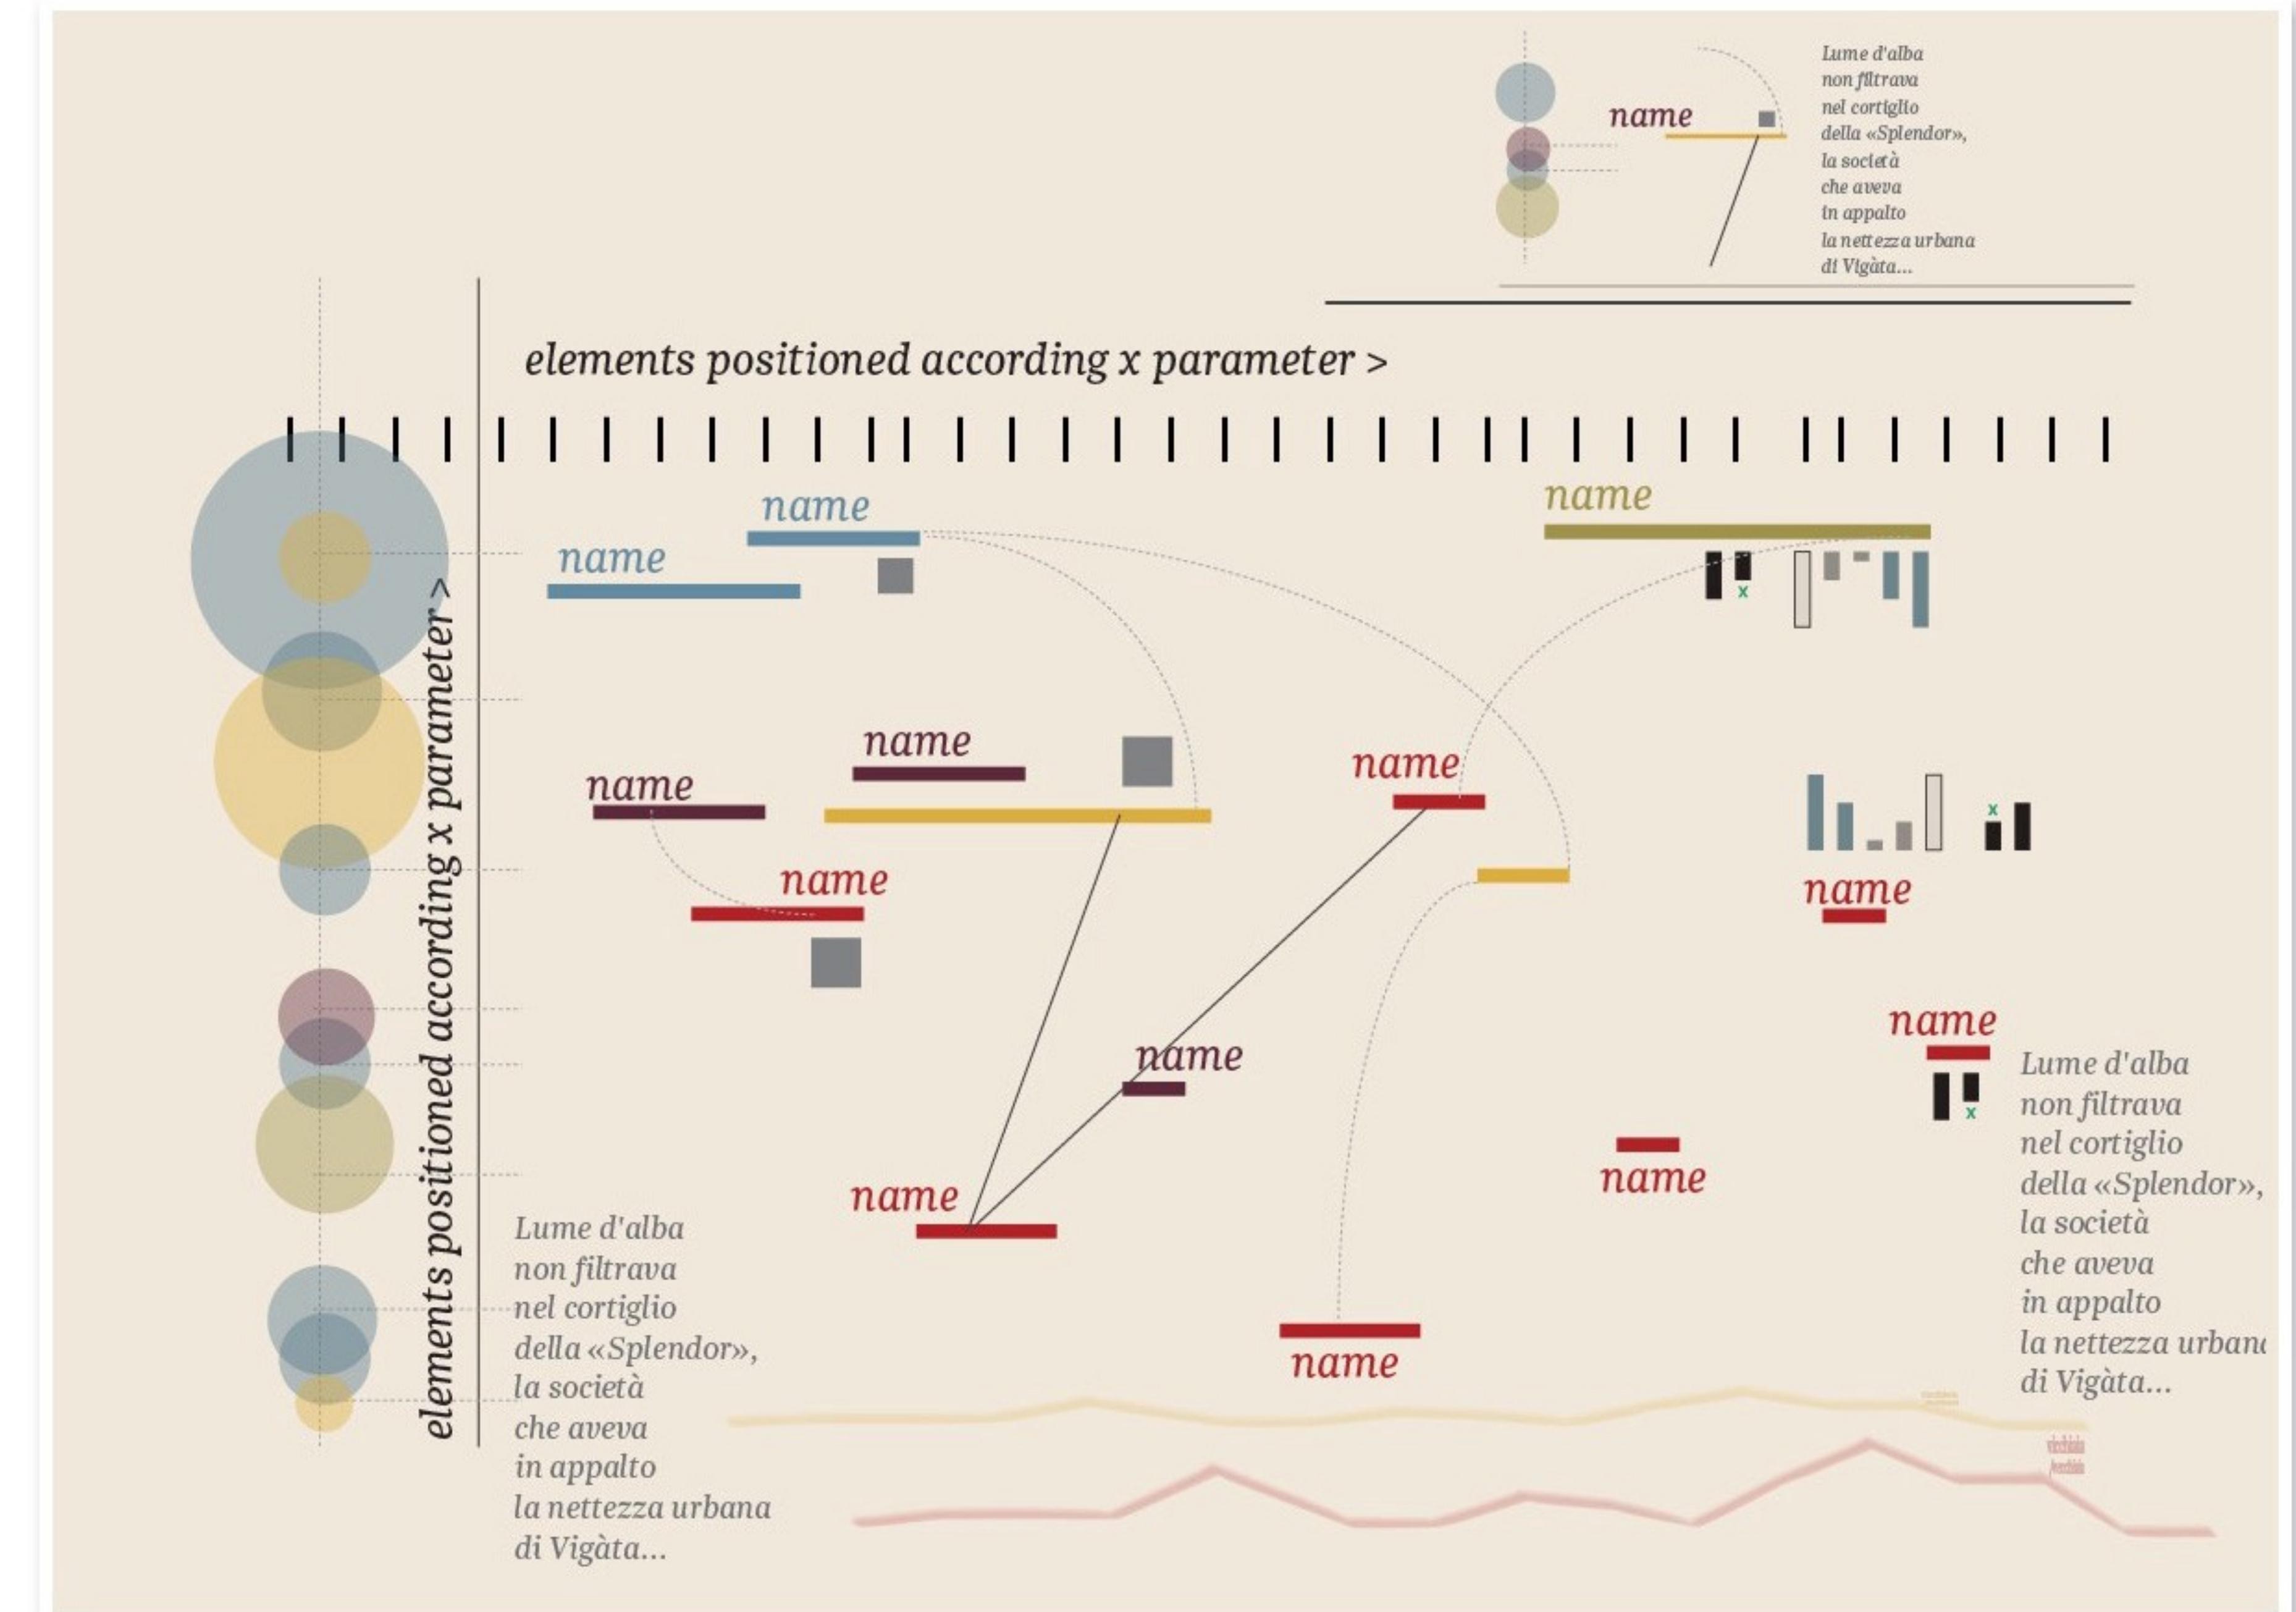

## [6] Supplementing the greater story through the addition of minor or tangential tales elements.

We consider this a very important step to contextualize the phenomena in a wider world. These components link the story to external ideas, other times, or other places. Elements that are rendered here may come from very diverse sources—analysis that is undertaken once we have strongly established the core story. These elements, which may take the form of small images, textual components, graphic symbols, etc., are to be located where they best help to enrich the overall comprehension: they must not distract from the main story.

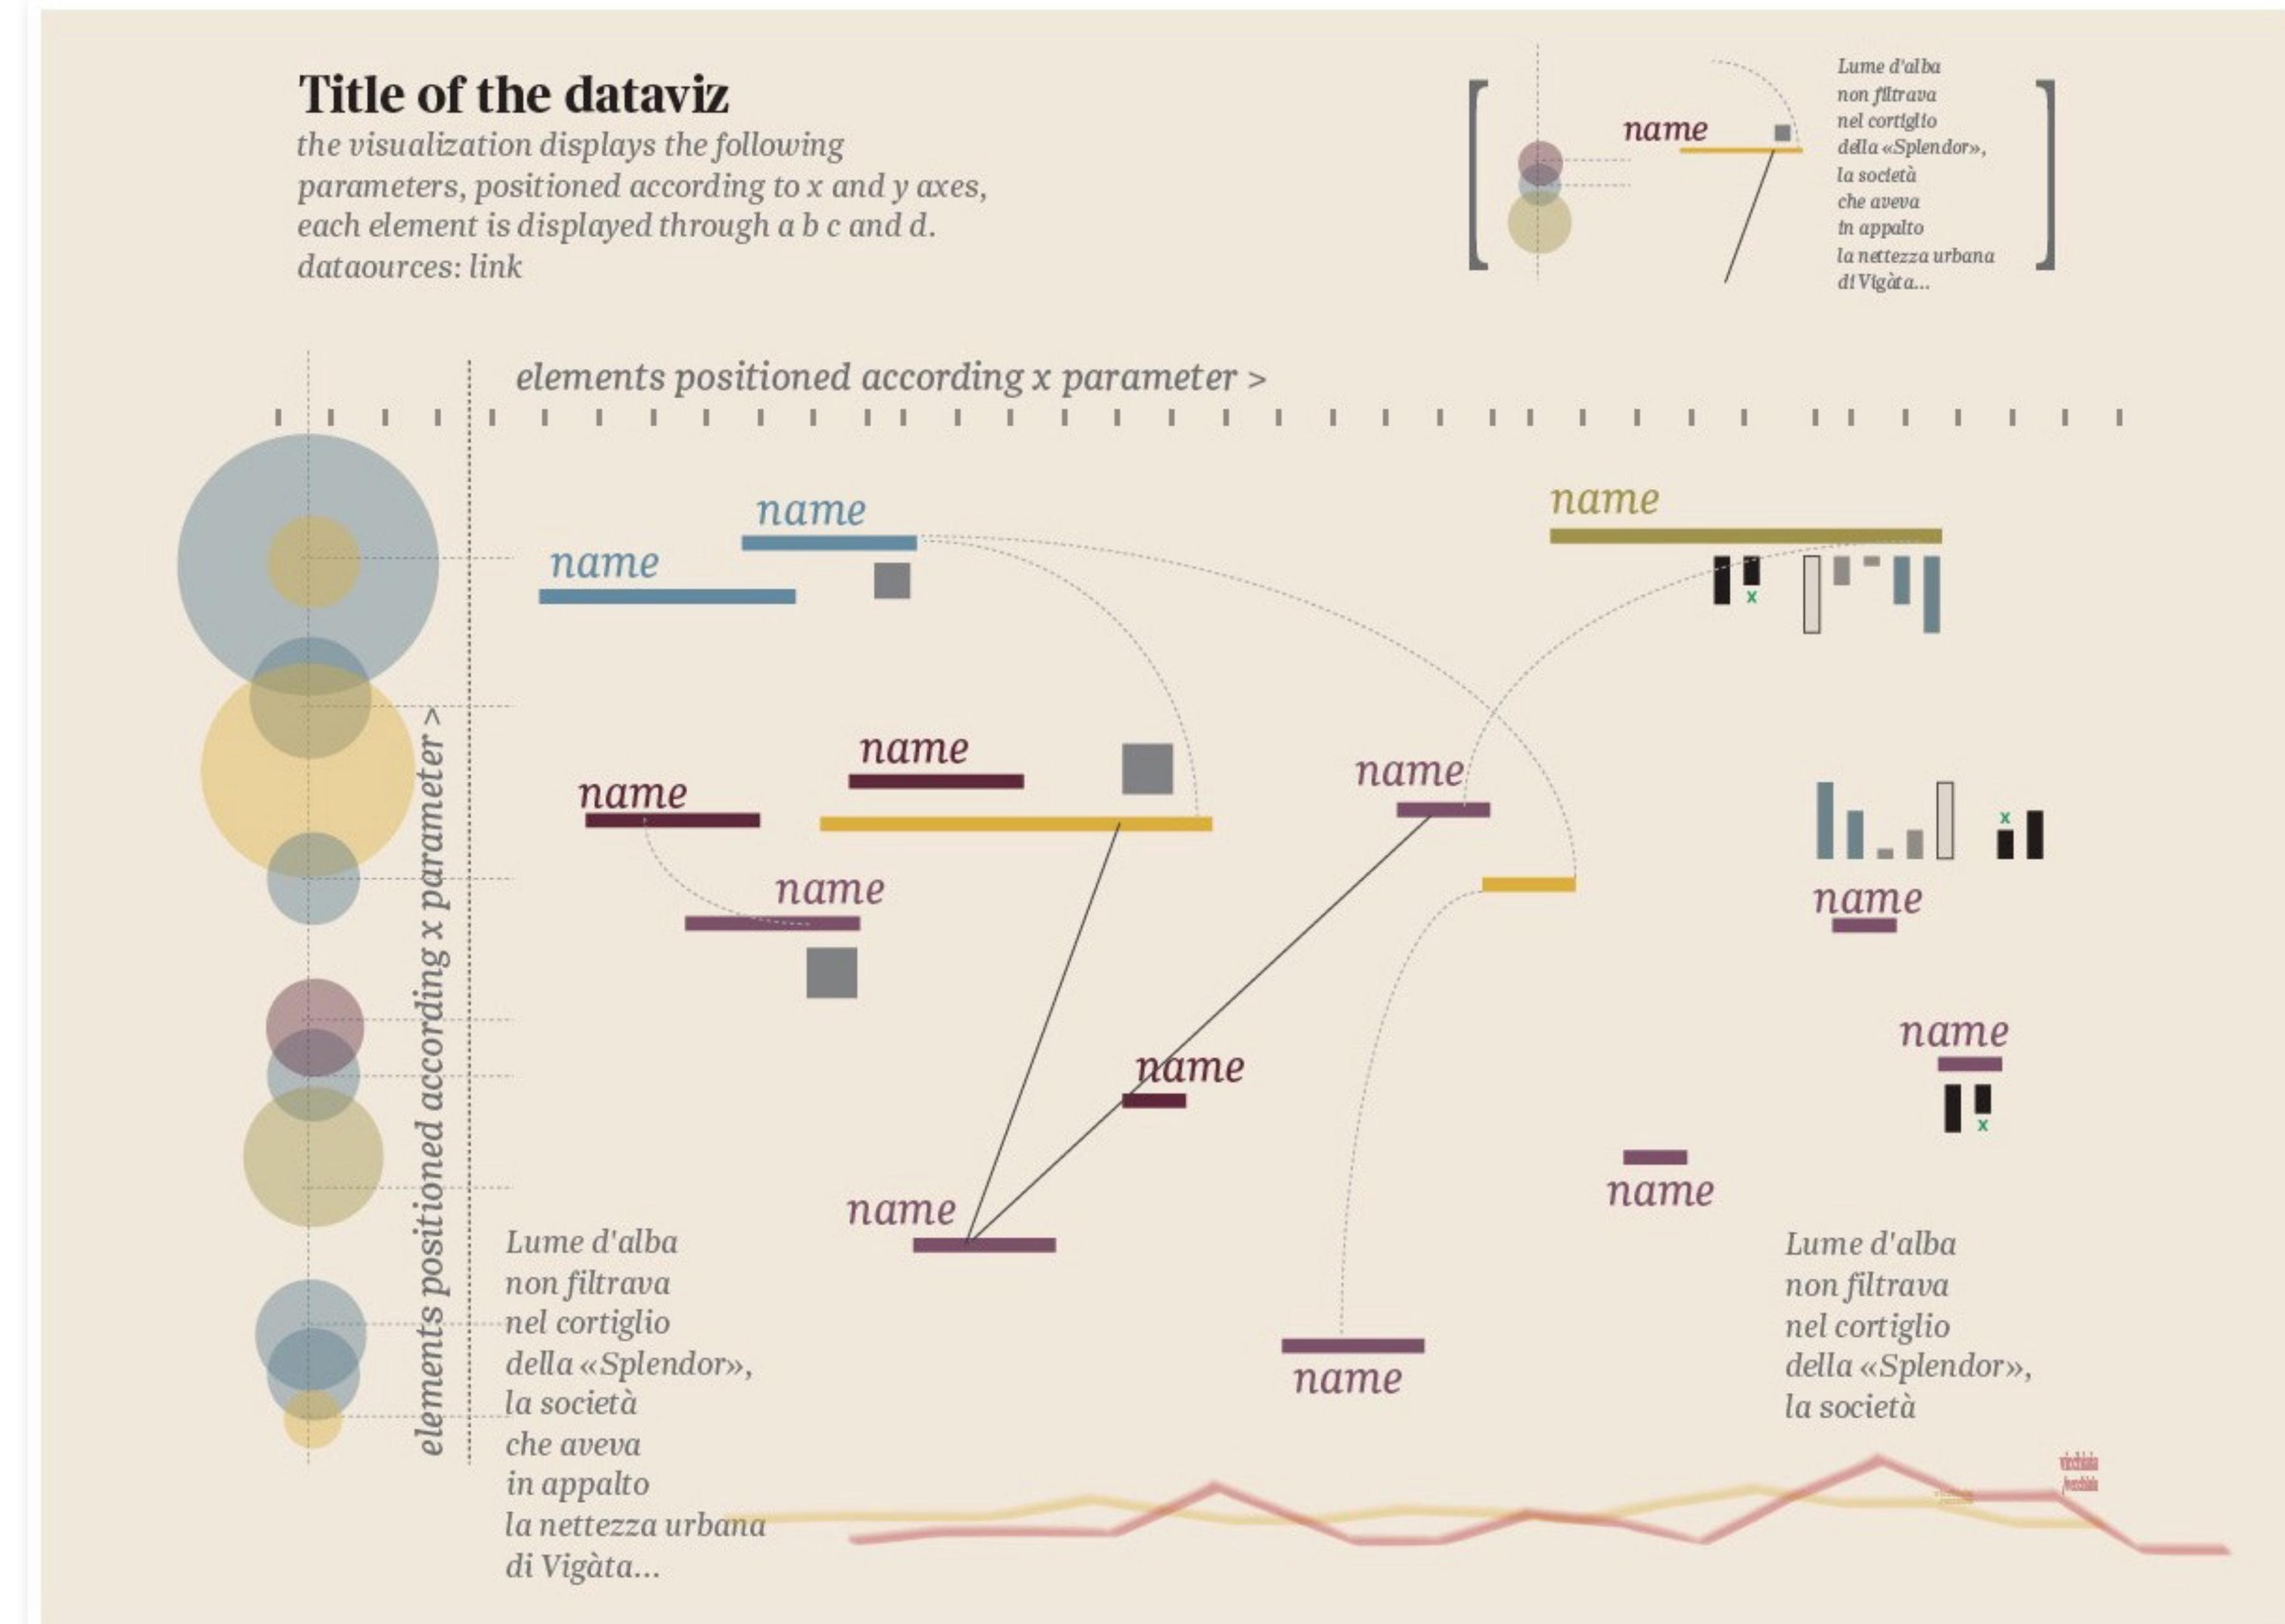

**[7] Providing small visual explanations such as a legend or key that assists readers and the general public who may not be familiar with norms of data visualization.**

These are composed to enlighten the layered idea of the visualization, often constructed as miniatures of the layers themselves. The process usually involves simplification of the general architecture (e.g. the x and y axes, base timelines, or map components) as well as minimal explicit shapes, colors, and dimensions of singular elements. These explanations also provide units of measurement for distances and volumes.

## [8] Fine-tuning and stylizing of elements' shapes, colors, and weights to make hierarchies pop out.

By visually highlighting the most relevant elements and lightening the other background layers of information, we should be able to allow information to be selectively and sequentially revealed, helping readers discover stories by themselves and recognizing the patterns or interrelationships from one element within the story to another.

# Winner, Information is Beautiful Award

## *Lupi & Fragapane, et al*

Lupi heads a design firm and this visualization is a representative example from her series of exploratory data-visualizations originally published for La Lettura, their Sunday cultural supplement, spanning two years.

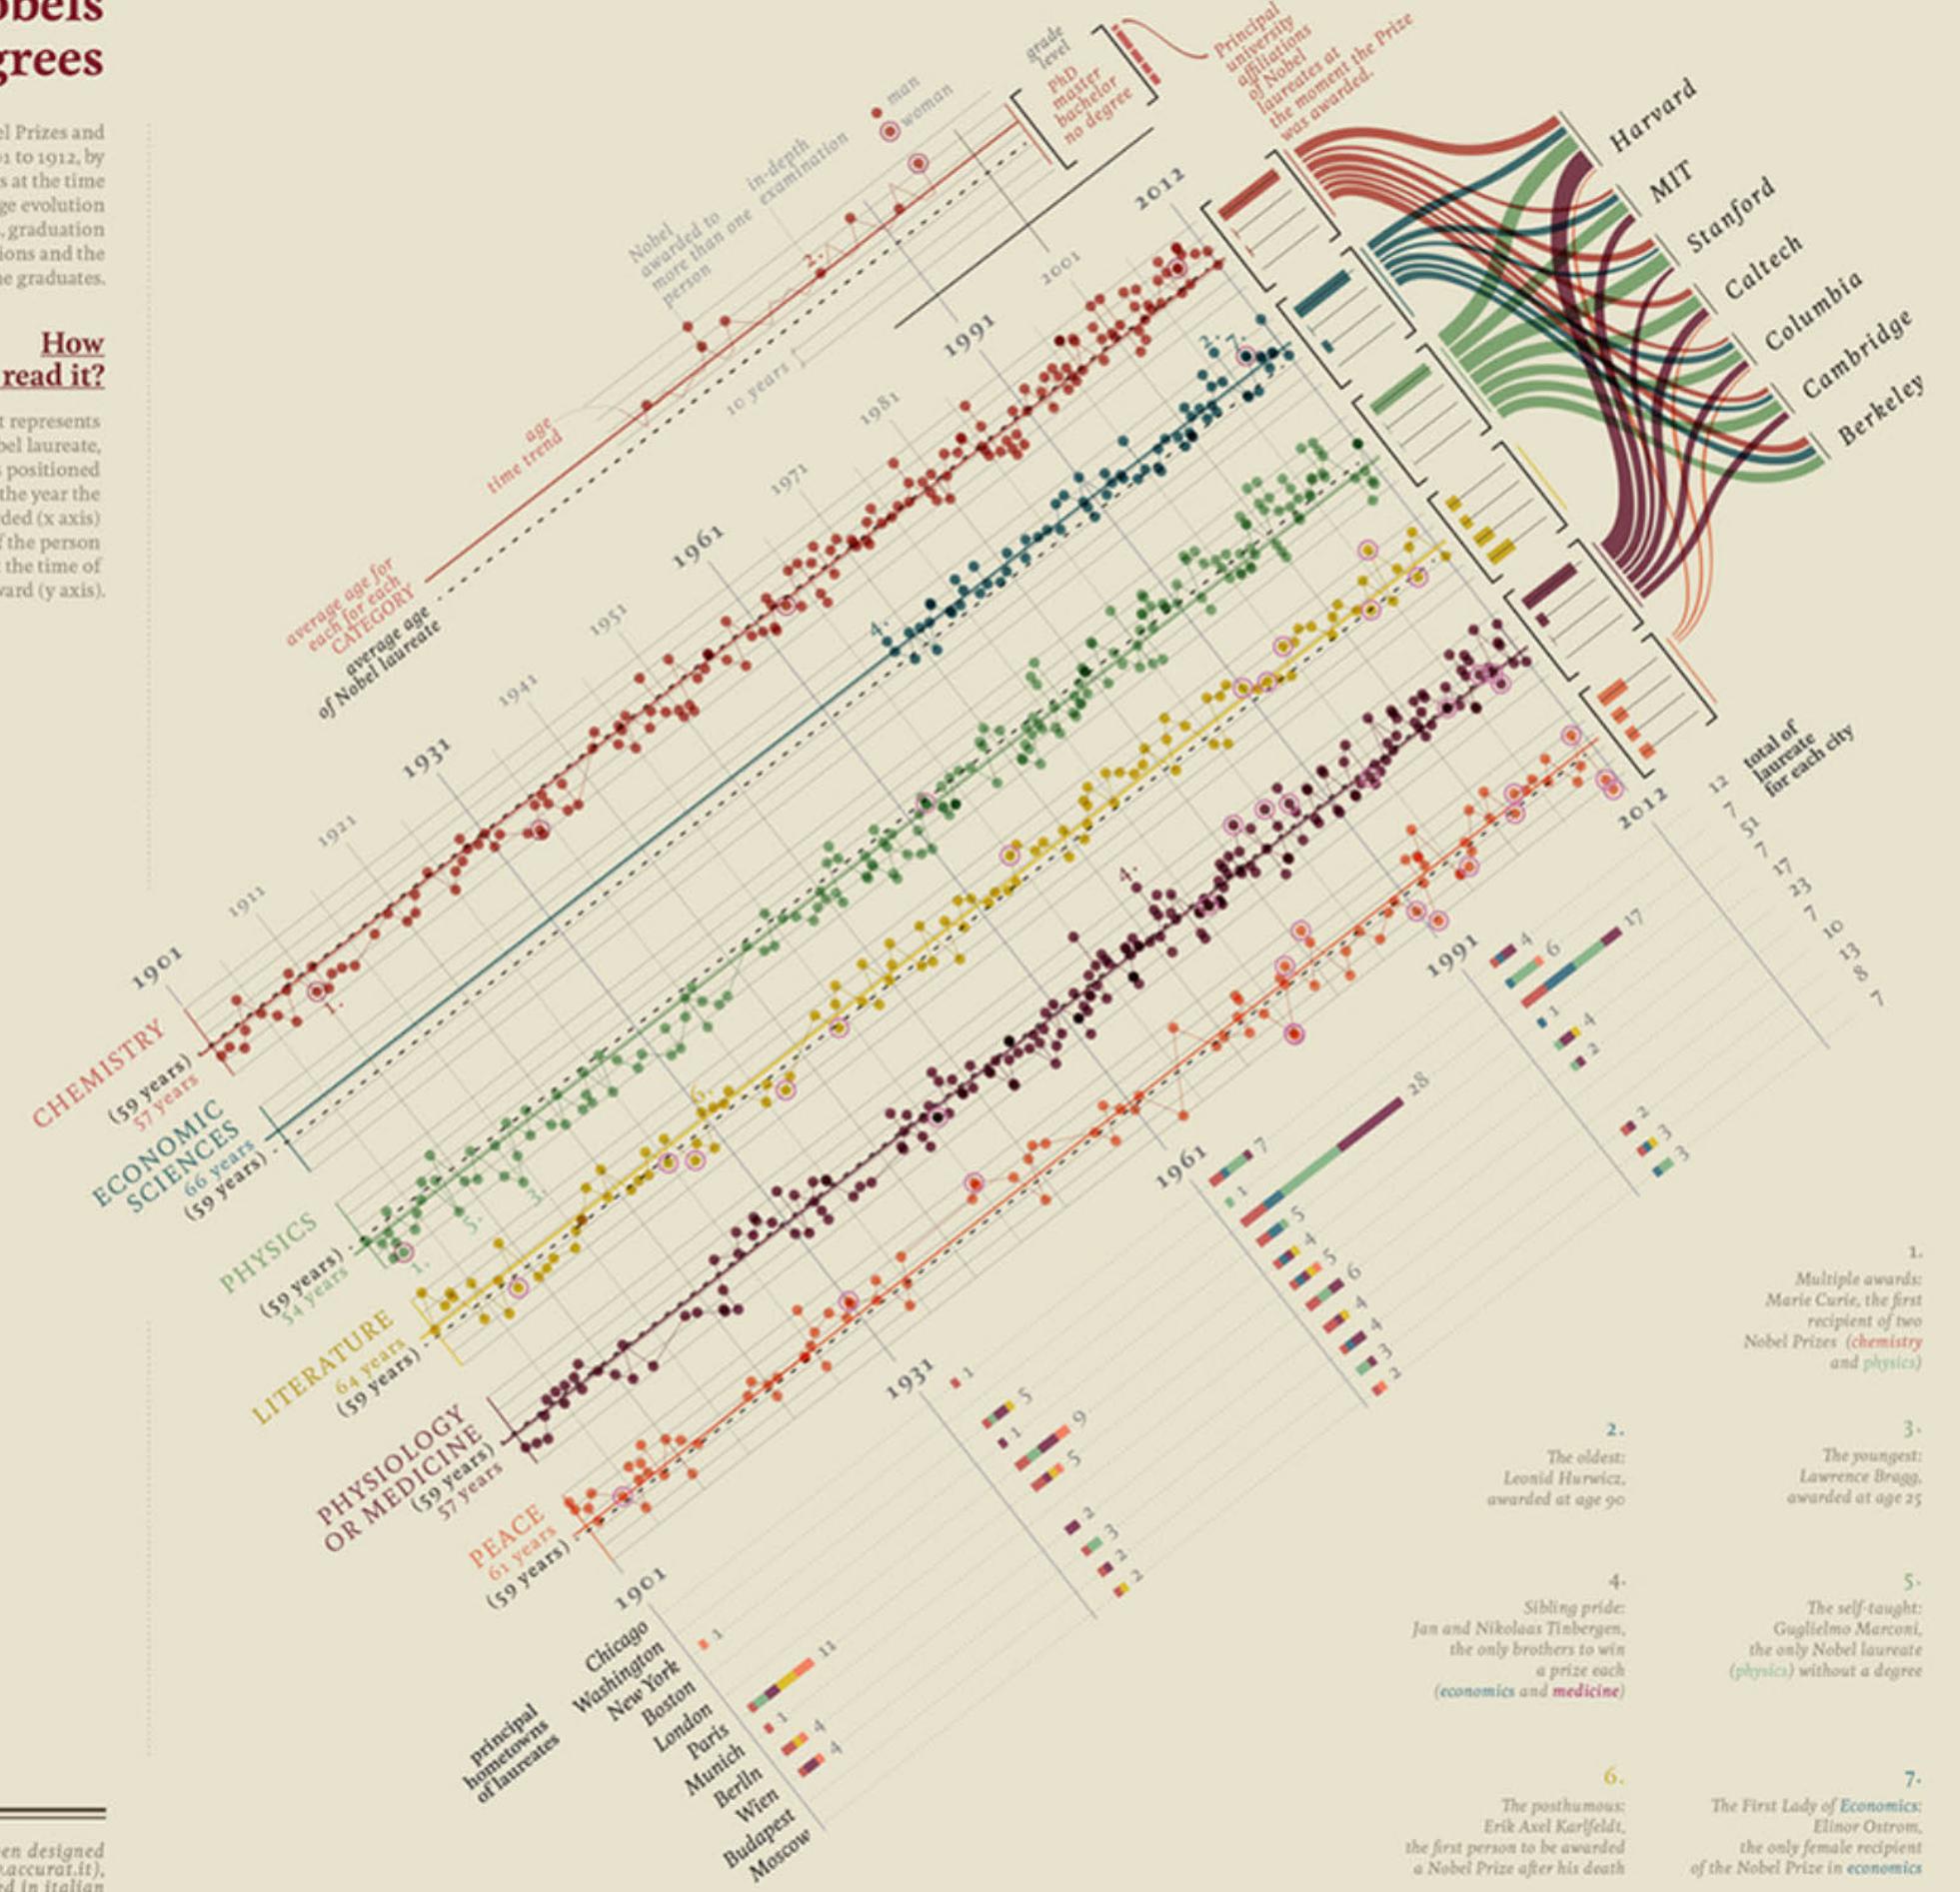

### Nobels no degrees

This visualization explores Nobel Prizes and graduate qualifications from 1901 to 2012, by analysing the age of recipients at the time prizes were awarded, average age evolution through time and among categories, graduation grades, main university affiliations and the principal hometowns of the graduates.

#### How to read it?

Each dot represents a Nobel laureate, each recipient is positioned according to the year the prize was awarded (x axis) and age of the person at the time of the award (y axis).

The visualization has been designed and produced by Accurat (www.accurat.it), and was originally published in Italian on *La Lettura*, the sunday cultural supplement of *Corriere della Sera*.

# Components are integrated with color, font—placement—lines, and annotation.

All four displays share data information. These relationships are integrated together using consistent color, in the case of prize categories,

and integrated using the relative placement of each display for both categories and other shared data. Placement of the histograms and Sankey diagram alongside the same categories in the central display reinforces the connection.

And notice, for example, that the per-era stacked bars share dates by aligning a common baseline with the x-axis of the central display.

## Nobels no degrees

This visualization explores Nobel Prizes and graduate qualifications from 1901 to 1912, by analysing the age of recipients at the time prizes were awarded, average age evolution through time and among categories, graduation grades, main university affiliations and the principal hometowns of the graduates.
